There are two sorts of houses used in Abyssinia, the beta nögus or round house and the sakala, whose ground-plan is an oblong square. The latter would seem to be imported from Yemen, for Niebuhr's plate of his reception by the Imam of Sana' gives an accurate idea of an Abyssinian sakala. But the beta nögus is essentially of Ethiopic origin, for it forms the great majority of dwellings from the Takazay in 14 deg. north latitude to Gobo under the 5th parallel. It is essentially a Chamitic feature, if we may believe the tradition universal amongst Abyssinians, that they are descended from Noah's second son. As the founder of the Pyramids, all Ethiopians, whether Abyssinians, Galla, Södama or Dawro, maintain that the interior of man's dwelling ought to be dark, and sunshine is looked on as a disgrace when falling on a table or couch. Almost all the modern churches of Abyssinia are beta nögus, as if the unconscious nation was relapsing into its primæval ways, but when the kings of Axum coined their own money, carried the tide of conquest down to the mouths of the Marab and Ansaba, or sent the sons of Tögroy to wage war against their Himyaric (?) forefathers, when Yared wrote his sacred music and lives of holy men, when Takla Haymanot planted the Cross in Damot and persuaded King Ytbarök to resign his crown, the prevailing taste was certainly for the sakala, as the

stone house at Abba Asfe, the ruins near Maryam Wagayro, the foundation of the Axum temple and the church of Abba Garima abundantly prove. Indeed, the oblong church of Kirkos in the isle of Tsana and that of Daga Astifanos, founded by Zar-a Yaögob in the same lake and towards the beginning of the fifteenth century, show that a love for the classical sakala continued long after the decline of Ethiopian literature and political importance. Herodotus tells us that the ancient Egyptians were descended from an emigration of Upper Ethiopians, and in Goudrou a singular confirmation of this is seen in a cave sided by natural obelisks, giving an exact prototype of an Egyptian temple. The Sidama in their ultima Thule preserve still the sacred fire, although but a spark, in carving their wooden tables, chairs and door-pieces. In Abyssinia fragments of stone carvings in the church of Abba Penteleon, formerly a heathen temple, resemble Middle Age church tracery. The far-famed churches of Lalibala are paltry copies of Grecian and Byzantine models, and the ruins of Maryam Wagayro and Manna in Bagemidr were probably erected before sculpture was dreamed of. It would seem that an iconoclastic missionary preached Christianity in these remote regions, for with the exception of a few Portuguese stone-cuttings, there are no Christian sculptured imitations of animated nature, but the taste for moulding is as national as in the days of Sesostri, and finds a vent on church door-posts and in carving the tabot or wooden tablets for saying mass. These are often elaborately and sometimes exquisitely ornamented, but only in fanciful design, without a single attempt to copy nature.

### Pulpits in Churches.

The pulpit was anciently disposed towards the eastern part of the body of the church, but not in the centre of the aisle. Pulpits are now rarely to be found of an earlier date than the fifteenth century, when they appear to have been introduced into many churches, though not to have become a general appendage. Ancient pulpits of that era, whether of wood or stone, are covered with panel-work tracery and mouldings; and some exhibit signs of having been once elaborately painted and gilt. Mention, however, is made of pulpits at a much earlier period; for in the year 1187 one was set up in the abbey church, Bury St. Edmunds, from which, we are told, the abbot was accustomed to preach to the people in the vulgar tongue and provincial dialect. The most ancient pulpit, perhaps, existing in this country is that in the refectory of the abbey (now in ruins) of Beaulieu, Hampshire; it is of stone, and partly projects from the wall, and is ornamented with mouldings, sculptured foliage and a series of blank trefoiled pointed arches, in the style of the thirteenth century. In the refectory of the ancient conventual buildings attached to the cathedral church at Chester, is another ancient stone pulpit, apparently of the thirteenth century. In the choirs of cathedral and conventual churches, and in the chancels of some other churches, a movable desk, at which the epistle and gospel were read, was placed; this was often called the eagle desk, from its being frequently sustained on a brazen eagle with expanded wings, elevated on a stand, emblematic of St. John the Evangelist. Eagle desks are generally found either of the fifteenth or seventeenth century; notices of them occur, however, much earlier.

### Penrhyn Slates.

North Wales is the chief slate-producing country in the world; some beds were worked as early as the twelfth century. At Penrhyn the slaty series comprises green slates, purple slates, blue and purplish-blue slates, purple and red slates. Here and there bands of grit are met with, while conglomerates occur at the base. The large slate quarry of Penrhyn is probably familiar to all visitors to North Wales. The summit of the quarry is about 500 feet above the base, and the slates are worked out in terraces each about 40 to 45 feet in height. The beds of good slate are about 200 feet in thickness, and are of a rich purple colour, with green spots. The beds have yielded no fossils save some burrows of marine worms and very doubtful traces of Fucoids, termed *Choudrites*. The bluish varieties of slate owe their colour to protoxide of iron, the red and purple varieties to peroxide of iron. The green banding of the slates and the production of the large uniform masses of green are considered to be not only due to independent causes but probably to have occurred at different times. The ordinary form of variegation of the slates consists of nuclei chemically or mechanically formed and environed by pale green slate, the bleaching of which has been due to the abstraction of the greater part of the colouring oxides of iron. This banding and blotching of the slate was formed probably before the slate was cleared, and some of the purple slate has been changed into green at the junction of the greenstone dykes. An analysis of the slate at the Glyn Quarries, Llanberis, showed 60 to 66 per cent. of silica, 13 to 21 per cent. of alumina, with peroxide and protoxide of iron, &c. Dr. Sorby has attributed the pale blotches of slate to concretions lying in the planes of bedding. Slate has been worked also at Cilgwyn and Nantlle.

### Andrea Palladio.

The inclination of Palladio was decidedly for the antique; he even studied ancient tactics, and so well understood them that, being one day in the presence of some gentlemen practised in military affairs, he made some galley slaves and pioneers perform all the movements and military exercises of the ancient Romans without disorder or confusion. After the example of the ancients, Palladio always preferred constructing his edifices of brick, observing that the ancient edifices of burnt earth covered with composition remained more entire than those of stone. It is true that edifices of covered brick are more durable than stone, because the bricks being more porous receive the cement, and, binding all perfectly together, form one complete mass, whereas the pores of the stone being less prevent this union. Besides which bricks are lighter, and not subject to be calcined by fire. With regard to the convenience of Palladio's buildings, a great man has said that the most delightful habitation was a French house, opposite to a Palladian. This is reasonable; not that his internal arrangements were made without discernment; on the contrary, he took many precautions, but, like other celebrated architects, he was obliged to conform to the manners and customs of his time. Architecture, in matters of convenience, must vary according to the manner of living. He made his arrangements with relation to the age in which he lived; he certainly could not foresee the taste of posterity, and, could he have done so, and made it a consideration, he would have disgusted his contemporaries.

### GENERAL.

**The Subscriptions** for the memorial of Pasteur, which is to be erected in Lille, have reached 65,805 francs. M. Cordonnier, the sculptor, will exhibit models of the figures of one of the groups at the coming Salon.

**Mr. E. M. Leist** has delivered a lecture at the Plymouth School of Art on "Old Rochester," in which the castle, guild-hall, cathedral and other buildings noticed by Charles Dickens were described.

**The Seventh Ordinary Meeting** of the Liverpool Architectural Society will be held at the Law Library, Union Court, on Monday, April 5, at 6 P.M. prompt, when a paper will be read by Mr. W. Henman, F.R.I.B.A., architect of the Birmingham General Hospital, entitled "Hospital Construction," illustrated by working drawings, &c.

**Mr. George Dove** has presented to the Tullie House Museum, Carlisle, an urn found recently in making a trench in that city. It is of blue-black ware, slightly scored with diagonal cross hatchings, stands about 9 inches high, and contains the calcined and comminuted bones of a child from seven to eight years old. When found it was protected by a small triangular piece of flagstone, which did duty as cover.

**Mr. W. Halsey Wood**, architect, who attained a prominent position in Newark, New Jersey, died in Philadelphia on March 13. He was one of the few architects whose plans were selected for consideration in the competition for the new cathedral in New York.

**Mr. John Hutchison, E.S.A.**, Edinburgh, is sending to the fine art section of the Victorian Exhibition his bust in marble of the Queen, which was modelled from sittings at Windsor Castle in 1888.

**The Owen Memorial Statue** has been set up in the hall of the Natural History Museum, where it serves as a pendant to one of Charles Darwin. Mr. Brock has represented Sir Richard Owen as Hunterian Professor and holding a fossil bone in his left hand.

**Mr. T. Butler Wilson**, architect, of Leeds, has issued in pamphlet form the paper on "Modern House Interiors" which he read before the Leeds and Yorkshire Architectural Society.

**M. Albert de Meuron**, the Swiss painter, who gained reputation by his studies of Alpine hunters, died a few days ago. As one of the foremost artists of the Republic, he was associated with the organisation of the Swiss section in most international exhibitions.

**The Fourth Ordinary Meeting** of the Dundee Institute of Architecture, Science and Art for the session will be held in Gallery No. 1 of the Albert Institute, on Wednesday evening, April 7 next, at eight o'clock, when a few descriptive and critical remarks by the President and other gentlemen will be given on the drawings and testimonies of study to be exhibited.

**An Exceedingly pleasant conversazione** of the Architectural Association of Ireland took place on the 30th ult. in the rooms of the Royal Hibernian Academy of Arts, the hosts being the President and committee of the Architectural Association of Ireland. The entertainment was varied, and the surroundings, which included the pictures now on exhibition, contributed not a little to the enjoyment of the guests.

# The Architect.

## THE WEEK.

THE report of the special committee, or rather of the majority of the committee, that investigated the irregularities of the Works Department of the London County Council will not satisfy those who have been supporters of the system, and will amaze the great body of metropolitan ratepayers. In the first place, the holding back of the report of the minority is a suspicious circumstance. It is supposed to have been due to an oversight of the officials, but it is remarkable that the officials of the Council always are in error, while the Council never cease to be infallible. Then, again, the proposal to transform the works committee into a works board is a confession of incompetence. The consequences of having a body of men like the majority of the committee to control engineering and architectural works cannot be fully known, but it is not difficult to imagine their seriousness. If in any limited company so much weakness was exhibited there would be an immediate dismissal of the members, but the ratepayers do not resemble shareholders. The majority of the Council appear to consider that their own existence depends on the works committee, and if one dies the other cannot survive. Hence it is that the system of worthless authority must be continued at all costs, the only concession to public indignation being a change of name from committee to board and a reduction of the members. It was always maintained that London was only following the examples of provincial cities and towns in dispensing with contractors, but the report of the Clerk to the Council makes it clear that the practice of playing with works has been performed in London to an extent that is without precedent elsewhere. In maladministration of finances the London Council is unique, and the lapses would not be tolerated in any place where public opinion was properly exercised. It is a fatality that with the Council's administration one blunder is the cause of many, for reform or correction is impossible. Ostentation inspired the erection of an establishment in Lambeth on a scale which no contractor would venture to rival. But in order to conceal the waste of money and to keep the establishment going it will be necessary to expend at least a quarter of a million yearly. The wiser course would be either to dispose of the premises or to allow them to remain as "a folly" in order to serve as a warning to all the public bodies of England. The report of the majority is only another proof that the men it represents are irreclaimable, and that if the principle of municipal government is to be respected it will be necessary to set about a more thorough reform than has been contemplated.

THE libel case, PENNELL *v.* HARRIS and SICKERT, which came to an end on Tuesday, is one of those which suggest the poverty of the English language in technical terms. The defendants had said that some plates executed by Mr. PENNELL, and described as lithographs, were not entitled to be called by that name, because they were not printed from drawings which had been made directly on stone. There is no doubt that SENNEFELDER, when he devised the process, supposed that all work should be executed on stone. But for that purpose it was necessary for the draughtsman to be competent to work, as it were, backwards. To attain that power special training was needed. When it was discovered that a porous stone, if heated, carried off any figures, letters or lines which were produced by a greasy ink on a special paper, it became possible for every one who could write or draw on ordinary paper to become a sort of lithographer. The process of transferring and the heat required made the work on stone less perfect than on the paper. Accordingly, the original process was never superseded. The medals and honours awarded every year in the section of lithography of the Salon are not given for plates which are merely printed from stone—the drawing must be made on stone. For a long time it was not possible to produce figure or landscape drawings resembling those done in crayons unless in that way. But of late years a sort of paper has been in use which, from having a broken surface, allows of subjects to

be drawn on it, and, after transference to stone, plates can be produced which have many of the characteristics of those which are produced by the older method. There are, of course, limitations. Drawing on stone admits of more gradations than is possible when paper is used, and there can be vigorous contrasts. But an artist may select those subjects which are adapted to an inferior medium and treat them in such a way that the advantages obtainable by working on stone are unnecessary. Plates like those of LOUIS HAGHE, DAVID ROBERTS, J. D. HARDING, or HANFSTAENGL's great series from the pictures in the Dresden Gallery, could not be produced if artists were compelled to draw on paper only. Unfortunately no distinction was made when describing the two classes of work; whether produced on stone or transfer paper they were designated as lithography, and men who were unable to write or draw on stone became lithographers. It would be allowable to say of artists of that class that they did not follow SENNEFELDER'S practice, and would not obtain a Salon reward. But to hint, however obscurely, that they were putting forth plates derived from drawings on transfer paper as examples of the old-fashioned and more costly lithography, in order to obtain more profit, is libellous, and consequently Mr. PENNELL obtained 50*l.* damages. For the same reason we suppose it would be risky to say a drawing made with an etching pen was not an etching, although a reproduction might be published which would have some of the characteristics usually belonging to the plates which are printed from coppers. It is time for some new terms to be introduced if critics are to be preserved from costly actions for libel and friendships are to remain unbroken.

THE decision given by Mr. Justice KEKEWICH on Tuesday may have the effect of introducing some modifications in the list of things which are supposed to be fixtures. The action Viscount HILL *v.* BULLOCK related mainly to the contents of certain fixed iron cases which were set up in a gallery or museum at Hawkstone Hall. There could be no question about the cases but the stuffed birds and animals which were affixed to fragments of trees and imitations of rocks were considered by the defendant, as trustee in bankruptcy, to be only chattels, and therefore removable. It was argued that the removal of any of the objects contained in the cases changed the character of the fixtures, and would therefore be illegal. Mr. Justice KEKEWICH agreed that if the cases were emptied the gallery would cease to be a museum. But its original architectural character would remain unaffected. The contents of the cases could not be considered as permanent. They were added to from time to time, and changes might be required to uphold the scientific character of the collection. Lord ROMILLY in one of his judgments had said:—"I think it does not depend on whether any cement is used for fixing these articles or whether they rest by their own weight, but upon this—whether they are strictly and properly part of the architectural design for the hall and staircase itself and put in there as such as distinguished from mere ornaments to be afterwards added." Guided by the same principle, Mr. Justice KEKEWICH came to the conclusion that the objects in question were not annexed to the mansion house, and should, therefore, be considered as belonging to the defendant.

MUNICIPAL officers in England who have to take charge of sanitation, building or other work, often grumble about the variety of knowledge which they are expected to possess. But the most exacting of corporations in this country would not dream of seeking such qualifications as the authorities of Denver in the United States demand from the candidates for the post of building inspector. The following is the advertisement:—"The commissioner of inspection shall have charge of the inspection of buildings and parts of buildings, drains, drain laying, elevators, boilers, gas and electric fittings, gas and electric lights and all other apparatus and machinery requiring inspection and regulation, as the same may be authorised by ordinances; the inspection and control of electric wires, the inspection of weights and measures, the smoke nuisance, the erection and care of workhouses, charities and corrections, and the care of markets and public baths." The salary for the omniscient being is of course very modest.

## HAMPTON COURT.\*

WE cannot expect a foreigner to be always impartial, but there would be probably little difficulty in persuading a Frenchman that Hampton Court was, if considered as a suburban retreat for royalty, more fascinating than Saint Cloud; a Prussian could not fail to acknowledge it was more delightful than Sans Souci; and he must be an ultra loyal Austrian who would say it was not more varied than Schonbrunn. M. FRANCIS WEY, the French littérateur, said that his countrymen cannot walk through the palace or the grounds without regretting Fontainebleau, Saint Cloud and Versailles; but that effect we consider to be a testimony to the sort of domesticity which reigns everywhere at Hampton Court. It might have been planned for a monarch who had retired from business, and its homelike character is enough to compel an exile to think of the land in which he can claim some rights, although only of an abstract sort. But if nature and art have combined to present a charming aspect at Hampton Court, the place only yields its full delight to those who are enabled to conjure up ghosts. M. WEY was aware of that fact, and hence he endeavoured to enlighten his countrymen about the numerous associations which were inseparable from the rooms and the gardens. He showed them WOLSEY, in spite of his immense power, arranging like any common man for a lease of the grounds, and stipulating for a clause to enable his heirs to renew the lease for a further term. Then, after securing the ground, but not being able to discover an architect who was able to design an edifice which should have unity, majesty or regularity, the cardinal was compelled to be satisfied with "un grand amas de jolies constructions." But the inevitable *ennui* was not to be deluded by capricious planning. WOLSEY had scarcely entered into possession of his fairy palace when he was condemned to suffer within it from unsatisfied desires and perpetual regrets. At a time when the Louvre was supposed to be a donjon if compared with the enchanted court in Middlesex, and from Flanders, Germany and Holland courtiers were coming to test the reality of the wonders, WOLSEY knew he had created an instrument for his destruction. By handing it over to HENRY VIII. the day of wrath was postponed, but a death on the roadside saved WOLSEY from the scaffold. It would have been wise, added M. WEY, if the Surintendant FOUQUET a hundred and fifty years afterwards had studied with attention the history of Cardinal WOLSEY. And then he points out how SHAKESPEARE, the great and audacious judge of kings and courtiers, was not afraid to evoke the story of WOLSEY in the time of ELIZABETH and to present it again before men who had assisted in the original drama. If compared with the English poet, how small appears the courage of RACINE when he related the amours of LOUIS XIV. in the cold Roman pastoral tragedy of "Bérénice." In 1718 "Henry VIII." was by order of GEORGE I. performed in the hall of Hampton Court, and there where he had once reigned and succumbed WOLSEY could again cry out against the weakness of those who trusted a monarch's smiles. M. WEY also informs his countrymen of the interlaced monograms of HENRY VIII. and ANNE BOLEYN, symbols of lovers who were to be separated by a stroke of the headsman's hatchet; how JANE SEYMOUR by a timely death at Hampton Court was spared a like fate; how the sombre PHILIP of Spain spent his honeymoon enclosed in the rooms; how ELIZABETH and LEICESTER walked beneath the oaks which have remained discreetly silent; how JAMES I., the "Maitre Jacques" of HENRI QUATRE, presided there at conferences between Catholics and Presbyterians; how CHARLES I. found a refuge from the plague in it, and an asylum from a revolted people; how the property was sold to JOHN PHELPS and purchased by CROMWELL; how it was used for the marriage of one of his daughters, and for the lying in state of the dead body of another. Can we wonder if M. WEY believes that the heavens appear seldom to smile on a place where so many strange scenes were enacted, that silence reigns in it, and that even English visitors appear to be shades roaming through the gardens?

M. WEY was obliged to be sparing in his details through

fear of wearying his readers. But much else could be told concerning Hampton Court which would have interest for Frenchmen. What an excellent lesson on the superiority of French taste was given by FRANCIS I., when, in a conversation with the English ambassador about it, he said he had heard that the English king employed much gilding in his palace, especially in the roofs, while he was content to make roofs of timber finely wrought, producing effect by means of a diversity of woods in their natural colours. We need not wonder if the French king believed gold was employed in pavements as well as roofs. The Bishop of Bayonne, who visited Hampton Court with the French ambassador, stated that "every place did glitter with countless vessels of gold and silver." His description confirms the inventory of CAYENDISH, which recounts that "every chamber had a basin and a ewer of silver, a great livery pot of silver, some gilt and some parcel-gilt, yea, and some chambers had two great pots of silver in like manner, and one pot at the least with wine and beer, a bowl or goblet, and a silver pot to drink beer in, a silver candlestick or two, &c." We learn also that in the presence chamber was a cupboard with six desks or shelves containing gilded plate of the newest fashions, "and the nethermost desk was garnished all with plate of clean gold." WOLSEY did not keep his plate only for show. When he returned one day, booted and spurred, he found the Frenchman awaiting him. Without taking off his riding-habit he called for a bowl of gold filled with hippocras, and drank, first to King HARRY and then to FRANCIS. Then "he desired the Grand Master to pledge him, cup and all, the which cup he gave him;" and some of the suite appear also to have carried off cups.

When WOLSEY obtained his lease there was a manor-house at Hampton Court, but no part of it has survived. The cardinal needed a more capacious palace than the king, for unbounded hospitality was to be one of the elements of his diplomacy. WOLSEY would necessarily have definite ideas of what was needed, and we may therefore assume that whoever prepared the plans was simply following instructions which the minister had furnished. It is true that WOLSEY, in reply to the king's question, professed that Hampton Court was not intended for his own use, but "to show how noble a palace a subject may offer to his sovereign." If, however, such was the intention, then WOLSEY must have failed to anticipate the royal requirements, and in that case was unfitted to be entrusted with the destinies of England. It was necessary for the king to undertake costly works as soon as Hampton Court came into his possession, which is evidence that the buildings, however well adapted to suit WOLSEY and his train, were in a great measure useless to HENRY VIII. As it is now impossible to prepare a plan of the cardinal's buildings, the question of purpose cannot be determined. But we may assume that SKELTON, a contemporary poet, was correct when he imagined multitudes gravitating round the cardinal—

To whose magnificence  
Is all the confluence,  
Sutys and supplycacyons,  
Embassades of all nacyns—

and that WOLSEY made provision to accommodate his visitors.

The selection of a riverside site so far from town was, moreover (if a tradition can be accepted as trustworthy), determined by a malady from which WOLSEY suffered. The water of a spring in Combe Wood was supposed to be entirely free from a calcareous deposit, and in order to have it at command he was supposed to have wished to reside in the neighbourhood. Whether that was the cause which brought WOLSEY to Hampton Court, or a very different one, or whether there was a thought of enriching HENRY need not be discussed. For all time the names of the two will be inseparably associated with the spot, and no discoveries of their different shares in the building can affect that union. But we can no longer judge of their palace in its entirety or test the worth of JOHN EVELYN's judgment when he said, "Hampton Court is as noble and uniform a pile and as capacious as any Gothic architecture can have made it." Uniformity and capaciousness are the qualities which belong rather to WREN's work, and from the necessity to attain them WILLIAM III. is often excused for his vandalism. However, the two styles side by side form one of the strangest

\* *Hampton Court.* By William Holden Hutton, B.D., Fellow of St. John's College, Oxford. Illustrated with forty-three drawings by Herbert Railton. London: J. C. Nimmo.

architectural contrasts we have in England. They are so unlike as to suggest not merely a revolution in politics, but one in national character also. The older style may recall despotism, but it has qualities which must always appeal to the English mind as recalling the past, with all its romance. Hence it was not without reason a similar style was prescribed for the Houses of Parliament, which should form the most national of all our buildings. WREN's innovations are more typical of a modern and scientific age, when the test of architecture was cost, and the picturesque had to succumb to utility. It was therefore to be expected that a utilitarian like FERGUSON should bestow more praise on the later work. He said, "WREN's design could have been made in a day. WOLSEY's bears the impress of long and patient thought applied during the whole time it was in execution, and though, therefore, the conception of the first is grander, the ultimate impression derived from the latter is more satisfactory and more permanent."

It is difficult for an artist to make illustrations out of two classes of buildings which differ so widely in character, and especially when he has a theory of his own about what is worth representation. It is evident that Mr. RAILTON believes with the Greeks that a part may be of more importance than the whole, and when a subject is commonplace it is not easy to apply that theory. He makes no secret of what he most admires, and in this case the Tudor work has the preference it deserves. At one time it is a group of chimneys and battlements on which Mr. RAILTON's eyes rest. At another it is an oriel window. ANNE BOLEYN's gateway is made interesting for its vaulting, and is a framing for the palace beyond. In WOLSEY's "confessory" the fireplace and the paintings are most emphasised, and in another plate the great oriel absorbs attention. In the banqueting-hall, on the contrary, the whole appears, for where so much is fascinating and feudal a selection is difficult. The haunted gallery has that indefinite appearance which ghosts might be expected to enjoy. The fish-court, the orange house, the old pond garden, the chapel court, the clock court, the master carpenter's court, the south-west wing are examples of picturesque drawing which have not been excelled in our time. Mr. RAILTON has never used a finer pen, and yet he somehow has contrived to impart as much breadth to his illustrations as if he had resolved to rival brush-work on a bold scale. Architectural drawing is so closely connected with bills of quantities, and has so often to be produced as if to supply evidence in a law court, it is no wonder that much excellent work is prosy by its completeness and precision. It is therefore a relief to contemplate drawings which are suggestive of enjoyment on the part of the artist, and which allow imagination to be exercised. Mr. RAILTON confers a sort of magic on his bits, and nobody who looks on them can suppose that so delightful a building is under the control of Government officials. The mystery is enhanced by the skilful treatment of the vegetation, which suggests continuous contrasts with the lines of the building.

When a young artist expressed his annoyance to GAINSBOROUGH about the hideousness of the fashionable hats of the period, the great portraitist told him to remember the light and shade which they subserved. The somewhat commonplace design of WREN which "could have been made in a day," and which is shallow enough to all who look on it, is compelled to yield effects of chiaroscuro such as WREN never anticipated. Mr. RAILTON's interpretation of the modern part of the building is the more remarkable to all who have tried to draw eighteenth-century buildings, because the effects had, as it were, to be made to issue under compulsion. It is not a clerk of works style that we see, but that of an artist who can linger over a detail until it becomes productive of beauty. The tact shown in making such diverse styles amalgamate without producing a disagreeable sensation is remarkable, and the young architectural draughtsman can derive invaluable lessons from Mr. RAILTON's plates, while the student of painting can see in them a respect for principles which are commonly supposed to be inapplicable when architecture is the subject.

Mr. HUTTON expresses the delight he felt in "wandering about with Mr. RAILTON, and of trying, under his guidance, to see the familiar scenes with something of his artistic inspiration. Curious nooks, quaint byways, courts

in which a stranger's footfall rarely sounds, here a solitary turret, there a garden that HENRY VIII. may have planned just as it now lies, have appealed with a new force as I saw how they had been or could be the subjects of the artist's most delicate draughtsmanship." But it is evident that Mr. HUTTON has also wandered about with guides of another species—with the spirits of those who have lived, and suffered and enjoyed in Hampton Court from WOLSEY and his king down to the respectable inhabitants of the palace at our time. The book is accordingly a production which is worthy of its subject, and will enable Englishmen, as well as strangers, to find more enjoyment in a place of which we may well be proud.

## ELECTRICAL INSTALLATIONS.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

(Continued from last week.)

### ARC LIGHTING.

A POINT to be considered in connection with the lighting of large buildings and grounds is whether the arc or incandescent lamp shall be used. This depends on several circumstances, such as capital outlay available, amount and effect of illumination required, and special conditions.

The electric arc is the most efficient method yet known of converting electrical or mechanical energy into light energy by means of heat. The reason of this is that the temperature of the electric arc is the highest attained. If a solid body is taken and heated up, the light given out increases rapidly as the temperature increases, and as the temperature required to volatilise carbon is very high—in fact, the highest known—it follows that the greatest intensity of light will be obtained from volatilised carbon, or more correctly carbon particles which are about to be volatilised. The efficiency of the arc is high because the arc is small, and consequently there is little surface from which the heat can be radiated, and the energy required to keep a body at a given temperature depends upon the surface, the emissivity of the surface at that temperature and the conductivity of the surrounding medium.

It is evident, using carbon in both an incandescent and arc lamp, that an arc lamp can be run at the highest efficiency possible with carbon, while the incandescent lamp cannot be run at a temperature anything approaching this, owing to the volatilisation taking place and breaking the filament.

To form a steady arc, it is important that the carbons should be kept at a given distance (within limits) for each current. The arc should not hiss, and it should not be liable to go out. The mechanism in an arc lamp is designed to automatically effect this, and to feed the carbons as they burn away.

The electromotive force required for a continuous current arc taking a current of about 10 amperes is about 40, and this pressure is usually allowed, together with a little extra to overcome the loss caused by the resistance of the cable, and the resistance in series with the lamp, &c.

There are two distinct ways of running arc lamps—in series and in parallel.

**Series Running.**—In the series system of working arc lamps, a dynamo is used which will give a continuous and steady current under all reasonable conditions, the voltage being altered to overcome the varying resistance in the circuit. The arc lamps are then run in series from this machine. Suppose that there are ten arc lamps each taking 45 volts, the voltage is then 450 volts; if ten more are inserted the voltage will be 900, and if one arc lamp only is used the voltage would be 45. To put out a lamp its terminals are short-circuited. For lamps to work under these conditions the important point is to keep the arc of such a length that the voltage is constant. The voltage required by an arc is greater when long than short, and consequently a fine wire solenoid is the important part of the lamp, and when the carbons (which are fixed to rods) burn away, and the voltage across the carbons increases, the extra current sent through the shunt coil pulls the carbons nearer together. A series coil is, however, usually used for striking purposes, and it opposes the shunt, *i.e.* when the current is not flowing the weight of the carbons brings them together, and when the current is switched on the series coil actuates a clutch

which grips and lifts the carbons apart. When this has happened its use is over, and the regulating is carried out by the shunt coil, its province being to keep the voltage of the arc constant by raising or lowering the carbons.

The clutch is an essential portion of any arc lamp, and exists in many forms which cannot be described here. It is, however, in brief, a mechanism which will grip a smooth rod or drum, if one part of the apparatus is moved a very little (by the regulating solenoid), and it will hold it with a very considerable force while the series coil will strike the arc. Also, as the carbon burns away, and the arc gets long and the shunt coil is at the end of its range, the grip will slacken and allow the rod and carbon to slip nearer together and so reduce the voltage. This action is called "feeding" and should occur very frequently and imperceptibly, *i.e.* the range of the motion of the clutch should be small so that the flicker will be very slight. The necessity in any clutch or brake mechanism is that the grip shall be strong and certain, that the clutch shall tighten and slacken with a very small motion, and that the mechanism shall not stick.

**Parallel Running.**—When arc lamps are run off, say, a 50 volt circuit, the conditions are very different from the above. The volts are kept constant by the dynamo, and it is the current that the mechanism must regulate and keep constant at the desired amount. The result is that in a parallel lamp the series coil will both strike the arc and also keep the current constant. The internal arrangement of a parallel lamp is the same as with a series one as regards the clutch mechanism. When the arc is too short, and the current rises, the series coil pulls the carbons apart, and when the current weakens owing to the extra length of the arc, the coil allows the carbons to approach.

**Series-Parallel Running.**—Of late years much attention has been given to the running of two lamps in series across 100 volt, four lamps across 200, or nine lamps across 400 volt mains. The difficulty has been that the voltage across all the lamps is fixed, but it is difficult to keep the voltages, *i.e.* the lengths of the arcs, constant in each lamp, although, of course, the sum of them is always constant. The result is that each lamp is alternately bright and dull, its own variations affecting the other one or ones. The consequence is often a rapid oscillation of the light. This has of late been much improved by careful regulation of the current coils and the abolition of dash pots (a piston fitting loosely in a cylinder which is filled with oil), or, in fact, anything which damps the action of the coils. The result is that the feeding in the lamps acts at nearly the same time, and the pumping or fluctuating action does not show so much.

The principle of enclosed arc lamps has already been mentioned and need not be referred to further, except to mention that the use of these lamps for running direct on 100 volt circuits has been very much extended. The efficiency is not so high as with two lamps in series, but the inefficiency is more than counterbalanced by the steadiness of running, the great saving in carbons and attention, and the more vertical distribution owing to the arc being longer, and therefore less obstruction to almost vertical rays, and consequently the shadow under the lamp is less than with ordinary lamps. This latter property is a distinct advantage for interiors and pavements in front of shops where a horizontal plane is to be illuminated as evenly as possible, while the lamps cannot be placed high.

**Alternating Current Arcs.**—The use of alternating current arc lamps is not to be recommended for ordinary work, if continuous currents can be obtained. The total amount of light emitted by them for a given amount of energy is only a little over half that obtained from a continuous arc, also the light is distributed in exactly the same manner in an upward as well as in a downward direction. This necessitates the use of a reflector to throw the light downwards, and a further loss in the efficiency is the result.

Alternating current arc lamps may be run in series, parallel, and series-parallel in exactly the same way as continuous current lamps, and the mechanism is similar. Three lamps can be run in series off 100 volt mains. The difficulty is chiefly that the coils have to be wound differently, and that the core of the solenoids must be of laminated iron. The reason of this is that energy will be wasted in the iron, due to eddy currents, if this is not done. Alternating arc lamp mechanisms are less liable to

stick than continuous ones, owing to the constant vibration which destroys the friction.

**Carbons.**—The very best carbons should be used for arc lamps; the positive carbon should be twice as large as the negative and have a soft core. The negative should be solid. In a continuous-current lamp the negative carbon is always underneath where the light is to be thrown down.

#### NOTES ON ILLUMINATION.

It may generally be taken that the arc lamp is the most suitable where a high illumination is required, and that in other cases the incandescent.

A uniform illumination is not always required and in some cases it is to be avoided, because the artistic and useful effect is often assisted by varying intensities of light. The minimum illumination permissible is a factor in determining the arrangement of lamps, and the average may be varied greatly by this.

The following general principles may be taken to indicate the lines along which the arrangement of lamps should run:—

1. With a given number of points, to obtain a uniform illumination place the lamps as high as possible. To increase the illumination increase the candle-power of the lamps.

2. With a given consumption of current to attain a high average illumination as uniformly as possible, use as many points and lamps of low candle-power as can be, and place them higher or lower as the uniformity or maximum illumination is more important.

A few figures giving the usual amount of illumination may be of interest.

Mr. PREECE'S rule is one 16 candle-power lamp 8 feet high for every 8 feet square (64 square feet). This is an average for rooms having fairly light wall-paper; it may need to be halved or doubled to produce the same result. The effect of wall-paper, &c., can be easily seen from the figures given in a previous article.

A 10 ampere arc lamp placed 18 feet from the ground will give a maximum illumination of about  $\frac{1}{2}$  candle foot, and if such lamps are placed 120 feet apart, they will give a minimum illumination of about .03 candle foot. This is hardly sufficient for interior lighting, and is usually greatly exceeded, but it is considered very good for street lighting.

Illumination of a surface is always compared with that produced on a small patch of it by a standard candle at a distance of 1 foot. This is the "candle foot" referred to above.

A rule which may be of use in determining the height of a lamp, whose candle-power is uniform in all directions, to give a maximum illumination on any point is that the distance of the point from the foot of the lamp-post should equal 1.414 times the height of post, or, in other words,

$$\text{height of post} = \frac{\text{distance of point}}{1.414}.$$

This rule applies to incandescent lamps with a fair amount of accuracy, but it does not apply for arc lamps. The maximum candle-power given by a continuous arc is, when short, at an angle of about 45 deg. from the carbons, and it is, of course, the same all round if the arc is burning properly. The angle of maximum candle-power of an alternating current arc lamp is at about 30 deg. above and below the horizontal plane of the arc.

This does not necessarily mean that the circle of maximum illumination on the ground is at this angle. The illumination on the ground is proportional to the candle-power, and inversely to the square of the actual distance of the circle from the arc. If the lamp is high, the circle of maximum illumination will be further away from the post than if low, but more evenly distributed, while a larger area will be illuminated with the same minimum.

The chief points to remember are that the utmost care must be exercised in the arrangement of lights to suit conditions of working, and that no exact rules can be given; arc lamps should be used where occasional hissing is not of importance, and where a high illumination is needed; and the height of the lamps and their candle-power for a given minimum illumination is greater where fewer points are allowed, owing to restricted capital outlay, than where many points of low candle-power can be allowed.

## TESTING.

The testing of an installation is often carried out in a very careless manner, and frequently by unskilled persons.

There are many points which determine whether an installation will be a success, and it can be easily tested if the right steps are taken.

*Wiring.*—The insulation resistance of every installation should be taken periodically, and the results are then of great use. The insulation resistance should be taken with the maximum pressure possible to be between any conductor and earth, and not much more and no less. If on a 100 volt three-wire system the testing voltage should be 200, and if on a 200 volt three-wire circuit 400 volts, and if a private two-wire installation at 100 volts, the voltage for testing should be 100 or a little over. If the current is alternating the pressure should be the declared multiplied by 1.414, or about half as much again as the average. There is no good purpose served by testing with a higher pressure, as this is the greatest the insulation is required to stand. It must be remembered that a high insulation does not always mean good work or that a low one means bad work. The insulation is often very low if the house is damp, due perhaps to fresh plaster, &c.

The insulation should be taken between each conductor with all lamps out of the sockets and the switches on; this tests with all the wire in circuit. The insulation should again be taken between each conductor and earth with all the lamps out and switches off. This will approximately test the insulation of each conductor from earth. It may be well, perhaps, to note here that frequently the earth leakage is taken with the lamps in and the switches off. This is to be condemned, because if there happens to be a connection between a fitting and earth, or there is a leakage from a lamp-cap, it will show as if the wiring is defective when it is not. It is very desirable also, from the consumer's point of view at least, that all his lampholders and brackets should be earthed. This is desirable, because in case of any fault due to a wire becoming connected to a fitting or leakage from a lampholder, it is impossible that exposed metal can be charged, and a shock is impossible. Unfortunately, some supply companies do not see things in this light, and make regulations that all fittings and lampholders shall be effectively insulated from "earth," this with a view to preventing "earths" on their system even if a fault occurs. This is really a mistaken view of the matter, as it makes it possible to have a number of poor "earths" distributed over their systems without being able to detect and order the removal of any of them. If, however, the plant is a private one, it is better in every way to "earth" fittings as much as possible, and this will not be objected to.

Notice should be taken if the insulation of a building comes out low, to see if the braiding is touching the bare wire at the switches, ceiling roses, &c., and if this is so it may explain a low insulation to earth, as the braiding is not supposed to be an insulator. There is, however, no danger in low insulation through this cause.

A thorough examination should be made to ascertain that brass screws only have been used for the covers of the casing, and it should be seen that floor-boards under which the casing runs have been screwed down and that brass screws have been used, or iron ones well greased. If this is not the case, the screws may rust in the boards and any future lifting of the boards will be very difficult. Even in supposed first-class work it will be often found that the cover is nailed to the casing when under boards, &c., where not seen. It has come under my notice where wires have been bunched in casing, that the fillet has been almost entirely cut away to make room for a greater number of wires than the casing was intended to carry.

*Joints.*—Joints should be examined to see if they are properly soldered and insulated. There is no need to give examples of bad joints, as so many have already been described in the technical press. A good joint should be strong mechanically before the application of the solder; the soldering should be good, done without the use of any acid cleaning mixtures and fluxes, and only resin or other approved flux should be used. The braiding should be cut away, and the rubber insulation tape solutioned slightly and then bound over tightly with pure rubber tape. However many T's may be taken off at one place, each

wire should be bound separately and filled up with the rubber tape until a little larger than the original wire. It should be impossible for water to enter the joint without first penetrating the rubber strip. The waterproof tape should then be lapped on carefully. Rubber solution should be used sparingly inside the rubber joint, but plenty should be put on the surface and on the waterproof tape.

*Lamps.*—It is also advisable to roughly test the lamps used on an installation to ascertain the current taken by them. It is often pointed out that a test of current is useless, unless the actual candle-power is obtained. This is, in my opinion, a mistake, and for the following reasons:—The actual amount of light given by a lamp is of no interest to the user, provided that it is sufficient. If an 8 candle-power lamp is wanted in a certain position, it is no comfort to know that the nominal 8 candle-power lamps are giving 16 candle-power and that their efficiency is good. The point is that if, say, twenty 8 candle-power lamps are required, lamps shall be used which give a sufficient light which will not take more current than twenty 8 candle-power lamps should do.

From another point of view it is a check on the lamp-maker to test the current taken by a lamp. The temptation is to make lamps, especially 8 candle-power ones, of higher candle-power than that marked, because low candle-power lamps are difficult to make. If the lamp-maker does make lamps of higher candle-power than the 8 candle-power ones, say of 12 candle power, the current taken will be high, and if the watts (volts multiplied by amperes) per candle-power (declared) come out high, it is a sign that the lamps are either bad as regards watts per actual candle-power, or that they have been carelessly tested and marked. The one fault is as bad as the other.

## HELLENIC ARCHITECTURE.

IN a lecture on "The Culmination of Hellenic Architecture in Attica" at the Glasgow School of Art, Mr. W. J. Anderson said he would look away from the historical and social influences, which, though none the less real, were largely hidden from the view of the artist of the time, and endeavour to take the standpoint of the master confronted with a particular problem. Applying this treatment to the Propylæa, the object of the building was considered, the alignment which Mnesicles, its architect, decided upon in its relation to the Parthenon and to the Acropolis wall, the angle of which its axis bisected; its central position being also designed to give on each side halls of corresponding size within and without the gate. The various obstacles preventing the accomplishment of the scheme in so far as they can be read in the building itself were considered, while the fitness of the architecture and the beauty of its details and painted decoration were shown by many illustrations. The Erechtheum was treated similarly, and regarded as a megaron in honour of Erechtheus, a monument-museum of many cults rather than a temple of any one or two, and in addition to photographs of its present state, restorations of its exterior and interior and of its relation to the complete Acropolis were supplied. Additional examples of the culmination in Attica were illustrated in the Hall of Initiation into the Eleusinian mysteries and the Temple of Apollo at Bassæ, the latter on the ground that it was the work of an Athenian architect. The second part of the lecture was devoted to the Greek theatre and games—the theatre, stadion and palestra—and in this connection were shown and explained the plan and restorations of the huge assemblage of buildings at Olympia, the apotheosis of athletics.

## SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

THE members of this Society paid a visit on Saturday afternoon last to the new building of the Prudential Assurance Company, in Pinstone Street, by the arrangement of the architects, Messrs. Alfred Waterhouse & Sons. There was a considerable attendance, among whom were Messrs. T. H. Waterhouse, C. Castle, W. Parkin, A. H. Holland, E. Winder, jun., T. Winder, C. J. Innocent (hon. secretary), Joseph Smith, C. B. Flockton, J. R. Wigfull, W. J. Hale and C. F. Innocent. Mr. Haigh (the clerk of works), as the representative of the architects, conducted the party over the building, and explained the various arrangements and the materials employed. He answered a number of questions asked by some of the younger members during their examination of the building. On the motion of Mr. T. H. Waterhouse, seconded by Mr. W. Parkin, and supported by Mr. Joseph Smith and the hon. secretary (Mr. C. J. Innocent), a very hearty vote of thanks was accorded to the architects and to Mr. Haigh (the clerk of works), who suitably acknowledged the vote.

## MODERN HOUSE INTERIORS.\*

THE architect in bygone days conceived and regulated not only the building but the whole decorative scheme of the interior, and frequently designed the furniture and minor accessories, whilst in close collaboration with him were the painters, sculptors and craftsmen, on whom, by his experience of them, he could depend to interpret his ideas; so that, although the work was not accomplished without the aid of many hands, yet the true cohesion and value of the various parts was obtained because the result was the outcome of a preconceived scheme formulated by one ruling mind. Is it not reasonable to suppose that the man who plans the skeleton should best know how to clothe it in a fitting manner and advise as to its proper aids and accessories?

Why, then, does not the architect more fully evidence his capability not only to control and design the shell, but to control and direct the internal decoration thereof? Are we to assume that the architect is, as a matter of fact, able to do this, but that, being a very haughty and exclusive person, he only deals with bricks and mortar, and leaves the unimportant question of decoration to the man in the street? Or are we to be charitable, and assume that the architect is of such a delicate and sensitive nature that he shrinks with diffidence from offering his vast knowledge and experience to the public? I venture to think that neither of these assumptions will commend themselves to reason. The fact remains that the architect stands aloof in silence—anything but a dignified silence—and allows the trade to deal with matters which should be to him the most interesting and important duties of his profession. And, moreover, his silence is construed by the public into something approaching a tacit acknowledgment of ignorance of the subject. Further than this, the suspicions of the public with regard to the architect's incapacity are more than negative suspicions. They are frequently confirmed by the difficulties found by the trade in clothing the skeleton left by the architect, who has designed the same without the slightest regard to an ultimate coherent scheme of decoration or furnishing. In short, the public of to-day are not quite sure of the architect as a decorative artist. The comparatively few and notable members of our profession who have distinguished themselves in this branch of art only demonstrate the truth of the old saying, "Exceptions prove the rule."

The great question then becomes, Are we architects to be content with this, or are we to make every effort to remove what is certainly a stigma on the profession, and restore the confidence of the public in us as artists?—artists of large heart, large brain, keen sympathy with everything beautiful, and with the great power of bringing all these qualities to bear upon all things connected with our profession. It behoves the architect of to-day to cultivate his artistic instincts and equip himself with the special knowledge which these instincts direct him to search for. The public once satisfied that the profession is largely contained of well-read, well-equipped men, competent to deal with internal decoration—the public, I say, will be only too willing to employ them. This done, our art would be restored to the confidence enjoyed in former times, and would become more and more potent in the future.

Now, to do all this the architect must be competent to control the whole of the work from commencement to completion. Self-contained, and acting independently of extraneous assistance, he will be strong enough in his knowledge to show both the public and the trade that this question is better understood by him than by others. It is of vital necessity that they be convinced that internal decoration and furniture is an integral part of his business. When by incessant application his energies have accomplished control of these things, then, and not until then, will the public respond with confidence.

You may say, "Yes, this is all very well; no doubt the leisured and artistic section of the public will do so, but what of the practical and busy portion of the community who adopt what is called a business-like view of the matter? What time have they to give even a thought to artistic cohesion and the unities?" Well, they can at least bring a considerable amount of business ability to bear on the question.

The architect, in his character as artist, accepts the duty of demonstrating beauties and truths to and for others whose time and opportunities for the discovery of which are necessarily limited, and in doing so exercises his professional acumen and primarily proceeds to treat with them on a question where they are at least both in touch, namely, the financial question.

A busy client wishes to build a house and obtain it at the most reasonable cost. He, of course, instructs that plans, quantities and specifications be prepared for the structure of the house, obtains tenders, and ultimately gets his building at the lowest market price consistent with his plans and specifications. He compares the figures of the lowest tender with those

of the highest, sees that he is saving the difference, and what is of more importance to us, sees that the commission which he has paid to the architect for definite plans, specifications and quantities has been money well laid out. The question of interior decoration and furniture then confronts him. How in these things is he to spend his money to the best advantage? He is naturally concerned with considerations of fitness and cost.

What is his usual proceeding? Does he not take the decoration and furniture into his own hands, being determined to get at any rate as near an approach to competition as he can, obtain designs and estimates from various firms, and form his own judgment upon their respective artistic and monetary qualities? But is he not keen enough to see that this is not true competition, the estimates received not being based upon the same designs and specifications, and most probably bewildered by the patter of the various salesmen and the variety of their designs, and finding the task difficult and costly, does he not give it up in despair, place his order with one firm and instruct them not to exceed a stated amount, with, more often than not, doubtful results? We know, all of us, that this is the case.

Now, I say that even the practical, busy man will gladly employ an architect, with artistic instinct and judgment, to prepare definite designs and specifications, and invite true competitive tenders for internal decoration and furniture. If I may be allowed to quote my own experience, it is that the preparation of definite designs and specifications by the architect is not only of the utmost advantage to the client from a financial point of view, but is also welcomed by the several competing firms, who fully appreciate the fact that they are tendering upon a similar basis. Of this I have had most emphatic assurances from members of firms of the highest standing, one of whom in a recent work remarks, "If we could only be sure that our architects possess the necessary knowledge and discretion, nothing could be more desirable than that they should undertake this work."

Whether altering the interior of an existing house or building a new one, with a view to ultimate decoration by us, a psychological study of the client should be our first consideration. Every man has an inherited or acquired ideal of what the atmosphere of his home might be. In some cases this ideal has shaped itself so definitely as to enable the client to express his views in a manner intelligible to the architect. In other cases this ideal exists unconsciously in the client's mind, and it is here the architect's duty to probe for and discover his latent ideal of home atmosphere. I hold that a man's home should be, to a great extent, an expression of his own better self—an expression moulded and guided by the hand of an artist reverent of traditional beauties and truths. If this psychological study of the client be neglected, the probability is that we shall provide him with a house, but fail to give him what he asks from us, namely, a home.

The next consideration is the internal economy of the house, having regard to its calibre, the social and family life of the client, the proper relationship of each apartment to its neighbours, the working of all departments. We must, in imagination, pass in and out of every door, ascend and descend the staircases and pre-apprehend inconveniences that would inevitably come to light when passing through the test of actual occupation. In short, no detail of domestic economy is to be considered beneath the notice of the architect who intends to plan a house which shall be at once convenient in its arrangement and economic in its working. Our client's assurance of satisfaction with the plans will not relieve us from the future criticism consequent upon the ultimate occupation of the house by him—that searching and merciless criticism to which all planning is ultimately subjected. The test, undoubtedly, comes with occupation.

Having assured ourselves of the proper organisation of our plan, we can then proceed to consider each individual apartment, and for its ultimate success it is indispensable that the complete scheme, embracing the disposition of the furniture, decoration, fittings, hangings, carpets, pictures and accessories should be in our mind. We should have informed ourselves of the nature of all objects which the client may already have in his possession, even though valued for associations' sake alone, and which will have to be reckoned with in the evolution of the scheme.

The principal considerations which dominate us are colour and form. Let me briefly allude to each of these. We give precedence to that all-important subject, colour, that universal source of pleasure, that essential and all-powerful element of decorative art. This subject has of late years been investigated to such purpose as to reduce the study of its harmonies and discords to a scientific basis. Colour should be considered before form, in that the wall space is the largest area of the room, and it behoves the colourist, I need hardly say, to select such colouring as will adequately harmonise, complement or contrast with the subsequently placed pictures, fittings, furniture and draperies. The size of the apartment, its aspect and

\* From a paper by Mr. T. Butler Wilson, architect, read before the Leeds and Yorkshire Architectural Society.

use, will govern us as to its particular colour scheme. The colour of the draperies, when the windows are isolated, may complement the wall colour. When windows are grouped together the draperies may harmonise, and thus carry the wall colour round the room. In constructional work, should hard woods and marbles, which carry their own colour, be used, they may be selected to contrast rather than harmonise with the walls. Should the constructional work be open to colour treatment, a decided complement is desirable.

The same order is then followed with regard to form, and whenever any of the materials are already in existence—for instance, pictures, wall coverings, draperies or furniture—examples should at once be seen. In fact, see as much as possible of that which makes your complete room, and see it in juxtaposition. You may then proceed to settle the form of the remaining items, working through from scale to full-sized drawings and models.

The complete scheme, but as yet only the scheme, having been decided upon, we then prepare the specifications and arrive finally at the most practical part of our labours, and I am disposed to think the most difficult, namely, that of preserving our tenderly nurtured scheme from the rough handling of the unsympathetic workman, by placing its realisation in the hands of the craftsman having the knowledge and skill requisite to produce the feeling which we wish transferred from drawings or models to the actual work. Those of us who have attempted to obtain this have realised by many a bitter lesson the dearth of such sympathetic co-operation.

But we are led to hope that encouragement from this and kindred societies in the work of the schools which have been founded for the training of workers in the applied arts, may yet result in the production of men qualified to carry out our highest ideals.

In conclusion, I say that the remedy rests with the profession to fix the highest standard of craftsmanship, and see that it is reached.

As a well-known writer has remarked, "However mean or inconsiderable the act, there is something in the well doing of it which has fellowship with the noblest forms of manly virtue; and the truth, decision and temperance which we reverently regard as honourable conditions of the spiritual being, have a representative influence over the works of the hand, the movements of the frame and the action of the intellect."

## TESSERÆ.

### The Impannata.

IF the artists of some Transalpine schools may be accused of sometimes employing the effects of a confined light for scenes supposed to take place under the broad atmosphere, the Italian painters (for the practice was not confined to the Venetians) must be acknowledged to have as often adopted the opposite course, viz. that of representing scenes in interiors as if seen under a diffused light. They appear to have thought that objects so illumined are more intelligible in pictures requiring to be seen at a distance (as was the case with altar-pieces), and that such effects are in themselves more large and beautiful. The effects themselves, though derived from the observation of nature in the open air, were produced by various artifices in Italian painting-rooms. The most common (still in use) was that of employing oiled paper instead of, or before, the glass of the window. A Madonna of Raphael's takes its name (*dell' Impannata*) from the oiled paper window, probably that of the painter's studio, in the background. The *impannata* strictly means cloth, but the term is also applied to oiled paper. Most of these contrivances, although not without interest as connected with the Italian practice of art, are obviously fit only for a bright climate; but the observation of nature and the technical expedients which were then habitual to the artists had also relation to the due effect of works in vast localities. It was the more essential to preserve the general appearances of nature in colour and light and shade because the forms in votive altar-pieces were often individual. Leonardo da Vinci, who is careful to distinguish between *ombra* ("the diminution of light") and *tenebre* ("the privation of light"), frequently recommends attention to the effects above described, and speaks of the modes (probably then common) of producing them. He remarks that objects seen in a diffused light are more beautiful than when lighted from a confined source, and that when represented in pictures they are more intelligible at a distance.

### Giovanni Scalfarotto.

Among the first revivers of a purer style in Italy was Scalfarotto, who, in the beginning of the last century, designed at Venice the church of San Simeone Minore, the first church in Italy adorned by an imitation of a genuine Grecian temple for its façade. Its unbroken entablature and pediment enriched with sculpture are supported by six disengaged Corinthian

columns. It is true that much fault may be found with the minor details of this structure, and its cupola particularly is much too high, but it is a great merit in the designer to have been the first to point out the road to real excellence at the very time when his countrymen were deviating the most widely from it. This example was soon after followed by Tirali in the front which he added to Scamozzi's church of San Niccolò da Tolentini, also at Venice; but we believe that these, with the two churches at the entrance of the Corso at Rome, are the only modern churches in Italy with an open colonnade in front of them, which is surprising, with the two ancient examples in the Pantheon and the beautiful Corinthian façade of St. Maria della Minerva at Assisi to invite imitation. Temanza, another celebrated architect at Venice, was scholar to Scalfarotto, and built the elegant Ionic rotunda dedicated to the Magdalen.

### Viollet-le-Duc as Professor.

Viollet-le-Duc had a great admiration for Napoleon III. and still greater admiration for the Empress Eugénie. Admitted to Compiègne through the influence of Prosper Mérimée, he concentrated all his cares on a little theatre which was set up in a corner of the château. The address he showed in designing costumes and scenery was appreciated. The courtiers used to say that Viollet-le-Duc was the only architect who was endowed with imagination, and if it were not for the jealousy of the Institut he would have been long before a professor. They considered there was no man so qualified for a chair in the Ecole des Beaux-Arts as an architect who comprised Vitruvius and Bramante in himself. During the interval which had to elapse before Viollet-le-Duc was recognised as the new grand master of French architecture it was decided to open a credit of some millions of francs in his favour, and the old château of Pierrefonds was handed over to him for restoration. In this kind of work Viollet-le-Duc excelled. He was an expeditious designer and possessed wonderful science; his knowledge of the Gothic period possessed a certainty that was inappreciable. His restoration of the Sainte-Chapelle and of Notre Dame is excellent, but he does not appear to have penetrated into the spirit of antiquity, and his ideas concerning modern construction seemed mediocre. It was, therefore, a surprise to many when he was nominated professor at the Ecole des Beaux-Arts. Mérimée had used his great influence with the emperor, but this time with an unhappy result. The pupils of the Ecole des Beaux-Arts were discontented, and protested. No attention was paid to their objections, and Viollet-le-Duc was solemnly installed in his office by the superintendent, the Comte de Nieuwerkerke. The professor being unable to utter a word owing to the clamour, left the theatre, escorted by the superintendent and some friends, among whom was Théophile Gautier. The students impeded their progress in the Rue Bonaparte, on the Quai Malaquais and the Pont des Arts. The crowd followed singing. Some collected in the court. Gautier wished to harangue the mob, and compel them to listen to reason. The law, however, is always the strongest. The police stopped him, and then locked him up. After dispersing the people, the police saw their blunder, and released the unlucky Gautier, who had already related the story of "The Courier of Lyons" to them. The end of the affair was that Viollet-le-Duc did not attempt to teach students who refused to hear him. He was most eager to have an audience, for at a later time, after the fall of the Empire, we find him seeking election to the Municipal Council of Paris.

### Louis Quatorze Styles.

The play of light and shade in sudden and varied contrasts is so essential an element of the Louis Quatorze styles that they do not admit flat surfaces in any of their ornamental details; all are concave or convex, perfectly smooth, but never flat—even the anthemion in these styles becomes a hollow shell. They thus contrast very strongly with the Elizabethan, in which flat surfaces in the details abound, as in its infinite strapwork; even in the cartouches, or pierced and scrolled shields, the curved planes are flat. All such members in the Louis Quatorze styles would be enamelled or moulded. This constant varying of the surface gives every point of view its high lights and brilliant contrasts, and for this reason stucco super-seded decorations in the flat and gold colours in all Louis Quatorze designs. The Louis Quatorze is more general in its aim than any style whatever; thus its details, provided they generated sufficient contrasts of light and shade, were of no individual consequence. Accordingly we find, after a little time, that all detail is absolutely neglected, and with it all study, and in the absurd Rococo—the very natural result of this general neglect—we have designs made up of details so without meaning and individuality as to defy description. They are Rococo; we can come no nearer to them, and with this Rococo, the first term of existence, the last of the nine lives of ornamental art expires.

## NOTES AND COMMENTS.

THE London County Council intend to apply the provisions of the Building Act of 1894 in order to secure that temporary structures for sightseers which will be used on June 22 are of adequate strength. Section 82 says that where a builder is desirous of erecting a building or structure to which the general provisions of the Act are inapplicable or inappropriate, application is to be made to the Council, accompanied with plans and particulars. If satisfied, the Council shall signify approval and the special or temporary building may be constructed. But as all the people who intend to let seats may not be aware of the law on the subject, it is settled by the County Council that notices are to be left at each house and posted in prominent situations along the line of route outside the City of London, intimating that the erection of temporary structures is unlawful unless the Council's license is first obtained, and that balconies intended to be used on the occasion must be shored up to prevent risk of accident. The Act limits the extent of the Council's interference to temporary structures. But in order to avoid all risk of danger to life and limb, it will be wise for those who let seats to make sure of the safety of floors and roofs. If we may judge by the advertisements, it is proposed to pack spectators within limited spaces as closely as possible. The loads will not be distributed over a floor while the procession passes, but will be concentrated in one part. It is true that part will be near the exterior wall, but it is well to remember that the floors and roofs of ordinary houses were not designed with the intention of accommodating extraordinary loads, and in fact no provision of the kind was made. Many of the houses along the route are old, and some which are modern are constructed as flimsily as the Building Act would allow. There is unhappily much ignorance among the ordinary tenants of houses about the weights which floors can sustain, and in the advertisements which announce capacious accommodation we have not observed in one any certificate from an architect or builder that the premises have adequate strength. We do not wish to excite alarm, but hirers of seats will do well to consider whether they are paying for a safe position, and if they have any doubt on the subject they should insist on a guarantee from an expert.

Cook Street in Liverpool has become an important thoroughfare, for it contains many offices which are used by prominent men of business. But a stranger who sees it for the first time is generally disappointed by its appearance. In one part the street is barely 14 feet in width. The city engineer has proposed to widen and improve Cook Street at a cost of about 27,000*l*. The subject came before the Corporation on Wednesday, when an amendment was proposed which would introduce an arcade 10 feet wide on the south side, and rounded off so as to give a continuous footway. The estimate would in that way be increased to 30,000*l*. There was much opposition, but eventually the amendment was carried by fifty-five votes to thirty-one.

At the beginning of May, Professor H. G. SEELEY, F.R.S., will resume the direction of the London Geological Field Class, which has been indebted to him for services since 1886. The teaching is of a practical kind, and is given in the field during excursions on Saturday afternoons. Short lectures are delivered upon rock structures and fossils seen in quarries, as well as explanations of the contours of the hills, valleys and river channels. The excursions illustrate the principles of geology, by means of facts which appeal to the eye, in scenery which is easy of access. It is proposed this season to visit Sheppey, Upnor, Rochester, Snodland, Aylesford, Maidstone and Tunbridge Wells. There will also be visits to Coulsdon, Godstone, Bletchingley, Leith Hill and Sevenoaks. Mr. R. HERBERT BENTLEY, 43 Gloucester Road, Finsbury Park, is secretary.

An American review has endeavoured to ascertain the cost per superficial foot of buildings in New York. It is not easy to insure accuracy in a calculation of this kind, but if the amounts obtained are only approximations, they are interesting. Frame dwellings, of the cheap two-storey

class, average in cost 3·71 dols. per square foot of ground covered, or 1·85 dols. per square foot of floor space. Brick dwellings of three storeys average 3·65 dols. per square foot of floor, counting nothing for the cellar; five-storey houses cost exactly the same, and four-storey ones, averaging the few examples found, cost a trifle less. Flats of five and six storeys average only 2·03 dols. per square foot of floor; flats with stores underneath cost 2·83 dols.; "stores and lofts," that is, ordinary mercantile buildings, give 3·12 dols. per square foot of floor, where the building is not over six storeys high. A six-storey hotel cost 3·33 dols. per square foot of floor, and a twelve storey warehouse a little less than 3 dols. Office-buildings of the "sky-scraper" sort are much more expensive, one of nineteen storeys costing 11·682 dols., and one of twenty-one storeys 12·34 dols. per square foot of ground covered, or 6·14 dols. and 5·37 dols. respectively per foot of floor-space. The calculations appear to be based on returns given by the Building Department of New York.

It is expected that in the course of a few weeks the second volume of Mr. EDWIN O. SACHS's fine work, "Modern Opera Houses and Theatres," will be issued. Owing to the liberal support afforded by the number of subscribers the author has been enabled to materially extend his original programme. No less than 300 well-known playhouses will be dealt with. Sixty theatres of recent date, representing Austria, France, Germany, Great Britain, Greece, Holland, Italy, Roumania, Russia, Spain and Switzerland, are fully described on 200 large folio plates in the first two volumes, and there are nearly 1,000 views, sketches and diagrams distributed in the text. Among the early subscribers were:—The Science and Art Department, H.M. Patent Office and other public authorities at home and abroad, the Royal Academy of Prussia, the Royal Technical College of Vienna and many educational institutions and public libraries. The private subscribers are headed by Sir HENRY IRVING and Sir DAVID SALOMONS, Bart. Mr. B. T. BATSFORD, of High Holborn, is the publisher. The third volume of Mr. SACHS's work will be ready in next December.

OFFICERS of a fire brigade should have some acquaintance with building construction, and the Dublin Corporation acted wisely in compelling candidates for the appointment of assistant superintendent of their fire brigade to submit to a competitive examination. There were twenty questions, of which the following is a sample:—If 29 cubic feet of brickwork weigh a ton, what weight will the supports of a shop-front have to carry, exclusive of weight of roof, floors and contents, the wall being 18 feet in length, 36 feet high and 18 inches thick, making no allowance for window openings? One of the competitors obtained no less than eighty marks in the examination, but he had to succumb to another who was able to gain no more than twenty-eight, being the lowest but one on the list.

A FEW weeks ago Mr. JAMES NEALE, F.S.A., architect, obtained an interim injunction to restrain the proprietors of a periodical from printing, publishing, delivering, or otherwise disposing of any copies containing plates from "The Abbey Church of St. Alban," the costly work of which Mr. NEALE is author. The volume was fully described in *The Architect* at the time of its appearance, when reproductions of some of the plates were given. The case came again before Mr. Justice KEKEWICH on Saturday last. The interim order was made perpetual, and the defendants were condemned in damages and costs.

## SALISBURY CATHEDRAL.—III.

THE Mediæval architects were not always strictly logical when designing the west front of a cathedral or church, for its relation to the building is not everywhere manifest. Too often the front is treated as an independent composition, which was to be judged by special rules. Salisbury is not one of the cases where architectural logic was dominant. That portion appears as if intended to serve as a sort of veil, and we cannot understand how an architect who in the rest of the building was so careful to express purpose, should in the west front have put together a number of parts which cannot be said to have any utility. But as among the Mediævalists there were occasionally builders who were negligent, so we must not be amazed if some of the designers considered the difficulties presented by the problem of a rational west front as insurmountable or not worth the trouble which a solution demanded. In many cases the opportunity was utilised of employing the front for the display of sculpture.

At Salisbury there were many niches formed for a series of single figures. The late Professor COCKERELL, R.A., calculated that there were 123 statues appearing in the west front. It was supposed that the whole formed an illustration of the Te Deum. It cannot now be stated with certainty in what order the figures stood, but after careful examination the following scheme was prepared for the purposes of restoration. In the gable is a colossal figure of the Saviour seated in Majesty. In the tier below figures of angels. In the second tier prophets and patriarchs. In the third apostles and evangelists. In the fourth and fifth saints, martyrs and founders. The remains of two figures of SS. PETER and PAUL proved that the arrangement must have corresponded with the order in which the figures originally stood. Among the founders Professor COCKERELL believed were figures of Archbishop LANGTON, Bishop POORE and WILLIAM LUNGESPÉE. The restoration of the west front was not confined to the statuary; before the late Sir GILBERT SCOTT took up the work every part stood in need of renovation or repair. The task was carried out with most scrupulous care, every portion of uninjured surface being preserved, and that which was destroyed being reproduced in strict conformity with the traces of ancient work.

There was another sort of restoration which could not be accomplished with as much satisfaction. We refer to the paintings of the roof. Salisbury Cathedral was not supposed to be pre-eminent as an exemplar of painting or sculpture, but there is no doubt that when perfect it contained works of both classes which were interesting. Mr. STREET once said on the subject:—

Almost all the earlier works which one visits in the Italian churches have (guide-books and cicerones notwithstanding) no claim to be called frescoes; they are nothing but tempera paintings. In England fresco was never used until quite lately. In the Middle Ages there was as great a passion for colour here as elsewhere, and our churches and public buildings were almost invariably decorated with it. It would astonish anyone not conversant with our old buildings to learn to what extent colour was applied. Generally it was a system of architectural colouring, with diapers and patterns, that prevailed; but the number of figure-subjects introduced was still something very extraordinary. In such works there was really a thorough combination of the work of the artist and the architect. The artist painted the angel or figure in the medallion; the architect directed the treatment of the decorative portion and arranged it so that it should aid, not spoil, his own handiwork.

The last words should be remembered by every critic of Salisbury Cathedral. The interior is supposed to be too severe as a whole, owing, among other causes, to the scarcity of sculptured decoration. But we cannot imagine all the compensatory effect which was produced by the coloured decoration that at one time appears to have covered the greater part of the interior. It was found necessary, in order to avoid giving too much surprise to a visitor, to employ colour in the western porch, the cloisters, and it may have been elsewhere on the exterior. Owing to the vandalism which was perpetrated in the interests of orthodoxy and the vandalism of a worse kind which was accepted as restoration, and the influence of time, which changes distemper into the lightest of dust, it is now impossible to make out the arrangement and subjects of the paintings on the vaulting without the help of guessing. In the last

century the remains of the paintings offended lovers of what was fitting and tidy, and, in consequence, buff colour was freely used to conceal their condition. But, as often happens, new washes cannot effectually hide the subjects which are beneath, for fragments are likely to survive. Some twenty years ago the old ornament and figures were sufficiently distinct to allow tracings to be taken from them, which, although containing blank intervals, were suggestive of the original character of the designs. According to a recognised practice there was a very large figure of Our Lord in a vesica in the centre of the nave, at the intersection of the small transepts with the choir. Important as was the painting it would be suggestive of spottiness if it were isolated. Accordingly, the parts of the nave and transepts near it were covered with large medallions of the evangelists, apostles, prophets, psalmists, &c., which were painted in a finer style than the parts more remote. On another part of the roof were medallions of the months, containing figures that were suggestive of common life. Apparently March was generally considered in England as the opening month of the year, but as the designer of the medallions begins with January, it is supposed he was either a Frenchman or followed the French or old Norman practice. The roof of the lady chapel was also painted. "Consecration crosses" of a more elaborate design than those found on modern churches are still to be seen over the western door and in the north and south transepts. Remains of painted arcading survive in the south transept, and some bold scroll patterns may be discerned elsewhere on the walls. Floriated ornament can be traced in the passage leading to the chapter-house. The evidence is therefore sufficient to prove that in the thirteenth century the interior of the cathedral, aided as it was with colour, and having, moreover, coloured windows, was no exception to the majority of the buildings of the time. In the thirteenth century there was no difficulty in finding artists who were competent mural painters. As Mr. KEYSER says:—"Many entries appear in the Court Rolls, &c. which mention the names of the painters employed, the subjects delineated by them, and the amount of remuneration received by them for their work. It is clear that at this time many foreigners were attracted to England, but the purely English character of most of the paintings of this date shows that this immigration served only to arouse a healthy competition on the part of the English painters, and to cause a marked improvement in the execution of the various works. It is generally supposed that many of the finest pictures were painted by travelling monks or other ecclesiastics, but even if this were the case, there is ample evidence to prove that both at this period, and still more in later times, abundant patronage was extended to professional artists, whose services were in constant request in the religious and secular edifices."

The restoration of the cathedral under Sir GILBERT SCOTT included many other works besides strengthening the tower. It was necessary to consolidate the foundations with concrete. The stonework in the lower part of the cathedral was repaired or renewed, and a channel coated with Portland cement was carried round the building. The earth which had accumulated against the walls to a height of nearly 3 feet was removed. The architectural effect was, of course, increased when the plinth and base mouldings were thus uncovered. The majority of the flying buttresses were in a dangerous condition. It was necessary to rebuild some of them. Finials, pinnacles, parapet coping and mullions throughout the building were generally dilapidated and decaying. They had to be made good. The decayed shafts, capitals and bases of the numerous windows had also to be restored. For that work Devonshire marble, which was supposed to be more durable and less costly, was substituted for Purbeck. In order to soften the contrast between the two varieties of marble, both were rubbed with oil until it was observed that the colours assimilated. The cathedral is, as a consequence of the expenditure of a large sum under Sir GILBERT SCOTT'S direction, likely to convince visitors for many years to come that Sir CHRISTOPHER WREN was correct when he said, amidst much which is condemnatory of Salisbury Cathedral:—"The incomprehensible sustainment of the various parts, although they have not any visible principle to account for their resistance to time and their own weight, yet shows the astonishing and consummate skill of the ancient architect."

### THE ARCHITECTURAL ASSOCIATION.

A MEETING of the above Association was held in the rooms of the Royal Institute of British Architects on Friday evening last, Mr. W. H. Seth-Smith, vice-president, in the chair.

Messrs. W. M. How and W. H. Purchase were elected members. A vote of thanks was passed to Mr. H. G. Montgomery for granting permission to the members to visit the Building Trades Exhibition at Islington.

The Chairman stated that the following house-list had been prepared:—President, Mr. H. W. Pratt; vice-presidents, Mr. Banister F. Fletcher and Mr. A. H. Hart; hon. secretaries, Mr. E. H. Sim and Mr. G. B. Carvill. Nominations for committee will be received till the next meeting, April 30.

Mr. T. G. Jackson, R.A., read his paper on

#### Architecture in Relation to the Handicrafts.

It used to be the fashion for any one writing or speaking on architecture to cite Vitruvius as the authority for what he said. The writings of Vitruvius are no longer regarded by everybody as the gospel of architecture, and, indeed, are now perhaps rarely read by architectural students. And yet on the present occasion I cannot do better than take as a text the opening passages of his treatise, which seem to apply very aptly to the subject for discussion to-night.

Vitruvius distinguishes at the outset between practice and theory in architecture, and goes on to point out that architects who are mere handicraftsmen without literary training are unable to give any reason for what they do, while those who trust only to theory and book learning without practical training seem to grasp at a shadow, and not reality.

An architect, he says, must be properly trained in both fields. He must be both ingenious and teachable, for neither will wit without training nor training without wit make the perfect artist. He must be a skilful draughtsman, a learned geometrician, not ignorant of optics, instructed in arithmetic, a good historian and a diligent student of philosophy. He must understand music, he must know something of medicine, he must be familiar with the decisions of the lawyers, he must understand astrology and astronomy. This is a formidable programme, and if one may without profanity speak disrespectfully of a writer who has hitherto been considered almost sacred, one would be tempted to say he was writing nonsense. The first part of his list is, no doubt, necessary enough, and as to the latter part, when we come to his explanations, we find that they do not make so much demand on the student as at first sight they seem to do. The usefulness of his historical lore is to enable the architect to explain the meaning of some of his ornaments, and to tell the inquirer that the figures of caryatids, which were used as columns, were derived from the matrons of Caryas, a Peloponnesian city, who were carried into slavery because their country had sided with the Persians against the Greeks. Philosophy is needful to him only in the same way that it is needful to everybody—to prevent him being arrogant and make him just, honest and temperate. As for music, he seems to require it principally for testing, by the note they give, the strain of the ropes of catapults and military engines. His knowledge of medicine should be sufficient to guide him to avoid unwholesome sites and bad water. As for his knowledge of law, Vitruvius seems to think he ought always to be an expert in questions of party walls, rights of drainage, and light and air. After this long enumeration of matters requisite for an architect, Vitruvius draws the line. Pythius, the architect of the Temple of Minerva at Priene, had said that an architect should be able to excel in all the arts, and in each to surpass those who made that art their especial study. Vitruvius thinks Pythius goes a great deal too far. An architect, he says, neither need be nor can be such a grammarian as Aristarchus, but he must not be unlettered; he need not be a musician like Aristoxenus, but he must not be without musical sense; nor need he be a painter like Apelles, but he must not be unskilled in drawing; nor need he be a sculptor like Myron or Polycletus, but he must not be ignorant of the plastic art; nor, finally, has he to be a doctor like Hippocrates, but he must not be without knowledge of the laws of health; nor in other studies need he excel as a specialist, but he must not be wholly unskilled in any of them.

To say that architects should excel in all these things is to demand an impossibility, because it is only now and then that a man can excel in one art even if he pursues no other. Pythius therefore is clearly wrong and has gone astray because he has not made a proper distinction between practice and theory. Therefore, says Vitruvius, he seems to have done quite enough in these several branches of study who has a fair knowledge of those parts and theories of them which are necessary to architecture, so that if he should be called upon to pass judgment upon or to approve these matters and arts he should not be found wanting.

Vitruvius, therefore, waters down, as he goes on, the somewhat strong dose which at first he seems determined to

administer to the student of architecture as a tonic necessary to his constitutional well being. A general theoretical knowledge of the various crafts which it will be his business to direct, sufficient familiarity with them all to prevent his passing indifferent work on the part of those who work under him, seem to be the measure of the practical acquirements necessary to an architect, according to the Roman authority.

On the other hand, we have the dictum of the Greek architect, Pythius, who says that the architect must not only have this general theoretical knowledge, but must be actually skilled in the practice of all the arts which he has to deal with, and not only that, but superior in each one of them to the specialist who follows only that single art.

Which of the two is to be our guide? Shall we be satisfied to be proficient in the theory of our art, learning it from books and lectures, and merely acquainting ourselves with practical work in a general way, enough to enable us to understand our specifications, and order the work properly, and detect flagrant instances of inferior workmanship and bad material; or are we with Pythius to put our hands to the work ourselves, and not only design but help to execute it; to train ourselves to be master craftsmen as well as superintendents and directors of other men's labour?

For many generations past the former of the two methods has been the order of the day. Most of us who have reached or passed middle age have been brought up under it, and if we have to any extent departed from it, it has been of our own initiation that we have done so.

That this plan was not that in vogue during the best periods of modern European art is well known. It was not in that way that the architects, or building artists of the Renaissance, in its earlier and more independent days, or those of the Middle Ages worked. They would have been at a loss how to go on if you had parted them from their building and their workmen, and shut them up with a drawing-board and a T square, and asked them to make their designs and convey their instructions by means solely of drawings. Their method was that of Pythius rather than that of Vitruvius, whose gospel, fortunately, had not in their day obtained currency, or been placed on the canon of inspired authorship.

I need not tell you that of late years there has been a revulsion against what I will call the Roman method of practising architecture in favour of the Greek. Many of us have been preaching against the strictly professional view of architecture, and urging that a man cannot be expected to produce good designs who seldom or never comes into contact with the materials out of which his designs have to be constructed. We have argued that it is from the handling of material that suggestions in design can most readily be gathered, that reading about processes in building, or any of the arts which go to make up a building, will never teach a man how to make the most of his opportunity, how to use his material to the best advantage, how to economise labour so as to avoid wasting it to no purpose, and how to design in accordance with the natural qualities of stone, iron or wood with which he has to deal. We have tried to impress on the student that an hour spent in the workshop or on the scaffolding will often teach him more than a week spent in a library. We have gone still further, and tried to persuade students not only to go and see how things are done, but actually to put their own hands to the work, and to become handicraftsmen in one or more of the many arts with which, as architects, it is incumbent on them to be familiar, and of which it is necessary the technicalities should be understood by anyone who undertakes to design for them.

These proposals, however revolutionary they appear to the advocates of the old-established professional system, according to which architecture has so long been practised among us, are still, it is clear, very far from bringing us again to the methods of the architects of 400 or 500 years ago, to say nothing of those of the Greek architect whose demands seemed to Vitruvius so extravagant. The contracts which bishops and chapters and others who intended building on an important scale made with their architects bound them down rigidly to a much more constant and intimate association with their work than a modern architect would submit to. The architect bound himself to come with his family and live in the place where he was to build, to engage workmen, and see that they did all that was necessary to be done, to work with his own hands, both in building and in sculpturing, as befitted a good sculptor and a master of the art of stone-cutting. He was also to go to the quarries as often as was necessary and arrange for the quarrying of the stone. Furthermore, he was bound for the term of so many years, during which the building was to be constructed, not to undertake any other work without the special leave of his employers, or a majority of them, or if he were engaged on some other building in the same or a neighbouring place, the time he should devote to each was strictly specified. Finally, he bound himself to supervise as chief master builder and superintendent all the labourers, builders, master workmen and handicraftsmen employed on the building, and to supply them

with such dimensions, orders and methods as would be required during the progress of the works. For all this he was to receive a fixed annual salary, to which was sometimes added a gown or two gowns in the year, and perhaps a house was provided for him to live in with his family.

The architect of those days, therefore, was a superior clerk of works, as we should call him, with this radical difference, that he had no master over him, sitting most of his time in an office perhaps 100 miles away, directing him by the penny post what to do, and sending him drawings to show him how to do it. Imagine a modern clerk of works to have had the training of an architect as well as that of a tradesman in one of the handicrafts—that is to say, to have the skill to design the work he directs; or, what is the same thing, imagine a modern architect to have learned one or more of the manual trades and to choose to go and superintend one of his own buildings as his own clerk of works, and you have the nearest approach to the architect who designed and raised the mighty structures of the past, which it is our aim to rival and our despair to surpass. He would necessarily be a mason to begin with, for masonry is the king of all the trades, the one which all the rest follow and the one which, blending itself, as it does, imperceptibly with sculpture—which is but a refinement of masonry—passes without any visible or marked transition into the higher region of fine art. In olden time sculptors and architects were the same persons, or at least, though there were sculptors who were not architects, there were probably no architects who were not sculptors capable of designing the carved work of their buildings, and of executing the most important parts of it, notably the figure-work, with their own hands.

Let us for a few minutes try to realise in our own persons what it would be like to practise architecture after this fashion. Let us shut our eyes to the present and try to open them again in the days of, say, Henry VI. or Lorenzo de' Medici. The dingy office in a London street vanishes from our sight. Away go the high stools, the drawing-boards, the dusty piles and rolls of paper, for—oh! blessed release—there will be no more working drawings to make and little drawing of any kind whatever. The office bell will no longer send a shock through our nerves, announcing the coming of a visitor to interrupt us at the most critical period of a design. The approach of post-time will no longer drive us into a frenzy to get off arrears of correspondence that cannot be postponed any longer, for we shall have little reason to write to anyone. Our employers will be on the spot with ourselves, and an occasional conference on the building itself will make much letter writing unnecessary. Away, too, goes all that tedious necessity of long railway journeys which dissipate our time, and exhaust perhaps four hours in travelling for every hour we have to spend on the work at the end of it. Our work will now be all under our eyes or near at hand, and the hours wasted in the railway carriage will be employed to good purpose on our growing building. Away, too, go the long specifications, the contracts with builders, the lynx-like supervision required to keep their performance up to their engagements, for we shall either be our own contractors or else have workmen under us employed and paid directly by the (our own) employer.

Relieved of all these official and commercial occupations, in which I venture to say most of us—do what we will—find half, and more than half, our time spent, we shall pass our working days clad in a workman's blouse, setting out our work on the ground, drawing such simple diagrams as will give the workman the proportions and dimensions of the several parts, marking out the mason's moulds, perhaps taking the mallet and chisel out of his hand to show him practically how we want certain parts finished, trying on the building itself as we can nowhere else the scale and proper character of our sculptured ornament, without doubt doing so much of it ourselves as will give the clue to the subordinate carvers, and probably finishing some of the most important parts with our own hands. Conceive the sureness and confidence with which we should work. There would be none of that experimental and hesitating anxiety which makes us doubt after drawing out a design whether it will come out as we intend in actual execution. No! there is the building itself on which to try experiments. When the thing is going wrong we can stop it at once and correct our original device and substitute something better, and there will be no contractor to worry us for an "extra," on the inevitable plea that the new way is more expensive than that for which he contracted. And so our building will rise, and as it nears completion and the scaffolding comes down, and we stand with hands behind us and head thrown back to see our creation as it emerges in its maiden whiteness from the enveloping veil of poles and planks, we shall feel that it is indeed our creation, the work of our own brain and in a measure of our own hands, in a way that no architect can quite feel now about any of his creations, however much pains he may have devoted to them.

This, gentlemen, I venture to think, will appear in the eyes of many of you—certainly to the younger men among you in whose bosoms the stirrings of art have all their youthful fresh-

ness—an attractive picture. Can we realise it at the present day? Or, if that is impossible, how can we get to it?

Can we get back to it? Well, of course, we cannot do it in a hurry. But can we expect ever to get back to the old system at all? I think not. It would be putting the hands of time back too far. Changes of system do not come about without some reason in the natures of things and of men, and to neglect the conditions of modern life in art while we admit their supreme influence in other fields would be not only unpractical but unphilosophical. Take, for instance, the matter of working drawings. The drawings used in olden time were of the slightest and most conventional kind. Even in Wren's time working drawings such as we make for every detail were not found necessary when competent workmen were employed. When sending his small scale plans and directions for the library at Trinity College, Cambridge, Wren adds, "I suppose you have good masons; however, I would willingly take a further pains to give all the mouldings in great; we are scrupulous in small matters, and you must pardon us, the architects are as great pedants as critics and heralds." In his day there were trained schools of masons and joiners who had traditions of their own and could be trusted to apply them. The architect gave them the size of the door, the scale and amount of ornament he wished to use in the doorcase, and the workman had sufficient skill to fill up the details of the sketch and to realise the architect's intentions as he would have them. So with the masons: to give them the moulding in great would, Wren seems to imply, be unnecessary if the men were good craftsmen. But where are the workmen nowadays who could be trusted to do this? It is easy to imagine the result if we tried the experiment. There are very many architects who do try the experiment of dispensing with working drawings, not from any desire to return to the older system of work as being better, but simply from the wish to save themselves trouble, or else in order to save their time for more lucrative occupations which have little or nothing to do with architecture. Some of them employ a ghost, and the ghost naturally takes little interest in a work which is neither his entirely, nor anybody's entirely, and the details come off badly. Others dispense with the ghost and leave all the details to a contractor. One builder told me that when he applied to an architect for details of a certain work the only answer he got was, "Take it and do it, and don't bother me about it." In another case the builder told me the only full-size details furnished him by the architect of a building which cost 6,000*l.* were those of a cellar door and a coal-shoot, and that he—the builder—himself made all the other working drawings, and did not even go through the form of showing them to the architect. Now I need not tell you that, whatever may have been the case in the days of Sir Christopher Wren, there is no school of workmen nowadays capable of filling in the details on a general design given them by an architect. Nor need I tell you that it is on the details of a design that its success depends for its ultimate appreciation no less than on the general conception, for no grandeur of idea or originality of scheme will make a good building if it is badly carried out in its details. An amateur may and often does have good conceptions in the mass, but it is only the artist who can carry them into execution successfully, because he alone is capable of contriving the parts out of which the whole general idea is built up. It may be imagined therefore what kind of architecture results from the method I have described, when the nominal architect gives only the rough idea of the building and leaves the details to men who have had no artistic training whatever. Indeed, there is no need for imagination in the case, for the streets of London are lined with buildings erected on this system, expensive and costly buildings very commonly, for the worst modern architecture is the most gorgeously decorated, and lavish expenditure on ornament is the last resource of an incompetent designer.

But if neither builder nor workman can be trusted to supply proper details for the carrying out of an architectural design, what conclusion is left to us but that they must be done by the architect? How is he to supply them? Of course he might, like the old men, go and live on the work, and give the details to the workmen by word of mouth, or by example, or by setting out the moulds and dimensions with his own hands. I do not know how many of you are prepared to follow your craft in this way. You would only be able to look after one, or at the most two or three buildings at a time, and though you would save the expense of an office, I fear 5 per cent. would not enable you to earn much more than a bare livelihood. Drawings, I fear, are, and must remain, a necessity if an architect is to have his designs carried out as he intends, and if he wishes to have full justice done to them.

Again, there are many buildings in modern times involving intricacies of plan which must be carefully plotted on paper, and could be contrived in no other way. Old buildings were very simple, and in their plans there was very little variety. One manor-house was arranged very much like another manor-house, and one cathedral or church on much the same general lines as another. Those buildings of our own day which retain

this simplicity of plan could be built without drawings just as the old ones were. It would be easy enough to build a great church from foundations to cap-stone of spire without a single drawing, or only such rough diagrams as the designer would need to enable him to put the parts of his building together. But when we come to such elaborate buildings as the modern town halls, or technical schools, or boarding-houses of our public schools, or theatres, or when we have to deal with confined and scantily lit sites, as in the streets of London, careful and elaborate plans are a necessity, and the drawing office indispensable. There is no prospect whatever of our being able to build in the future without drawings, and we may dismiss as impracticable all hope of superseding them by supervision and direction on the spot, and of being able to shut up our offices and take to the building sheds and the scaffolding.

But admitting all this—acknowledging, as I fear we must, that the necessities of modern system are too strong for us, and that we must in the main go on as we are now doing—is there nothing we can do to place ourselves more in touch with the handicrafts? If we cannot go the whole way, may we not go part of the way to meet those workmen on a common footing with whom, whether indirectly or directly, we cannot help co-operating in the carrying out of our designs? If we cannot, as Pythius would have us, excel in all the arts, so as to surpass in each one of them the skilled workman who has followed that one alone, and made himself master of it, surely we may, without being unreasonable, demand of our architects that they shall at least not design things without knowing how they are to be made. Nor if it is unreasonable to ask us to be better masons, better joiners and carpenters, better smiths and better plasterers than the men who follow those callings and do nothing else, is it unreasonable to demand that every architect should so far familiarise himself, by actual observation and inquiry, with every one of these trades, that he may know how to make designs suitable to the material employed and the way of employing it. And yet we are all our lives designing things without knowing how they are made. How is it possible we should not, in our ignorance, give a world of unnecessary trouble to the workman, cause a deal of needless expense to our employer, and miss altogether that propriety in design which arises from proper use of material, because the proper use of it is unknown to us? Take, for instance, the case of wrought-iron work. Every architect is called upon constantly to design such simple things as railings, grills, balustrades, in that material. He draws, probably, something after good examples that he has seen; perhaps he tries to improve on them and design something new, and if he knows nothing of smiths' work except from books and drawings and such sketches as he has made of his own, the alterations he makes very likely make what was very easy into something very difficult, if not impossible; and even if the workman gets over the difficulty by some troublesome device of his own, the labour involved is thrown away and might have been saved by a little knowledge on the part of the designer. Those who have only designed ironwork on paper and never seen it made, would be astounded to find how very differently it was done from what might have been imagined, and how very much more simply their design might have been done by altering it a little. I wonder how many in this room have any idea how so simple a thing as the ordinary forked baluster is made, with one foot to be let into the stone for each pair of balusters. I confess I did not know till the other day, when I wished to vary the form of the thing so as to give it a little more character, but began to doubt as I went on whether the smith could make it. So I went to the forge and had some experiments made, and found that the usual process was quite unlike what I had imagined. Another advantage of the visit was that I was able to suggest to the smith other ways of doing it, and before we finished we had made a forked baluster in four different ways, and found out what was the easiest and cheapest. This seemed to me an instance of the way in which designer and workman can help one another—the designer, from habit, seeing his way to fresh possibilities, while the workman, from habit, had not thought of doing anything but what he was used to.

Let it be a rule, therefore, with every architect never to design anything without knowing whether his design is practicable, and practicable according to the received traditions of the craft concerned.

But may we go no further than this? May we not require that he should be able to put his own hand to the work as a handicraftsman in one or more of the trades over which he has to exercise control in the ordinary discharge of his duties?

There are some trades of which it is obvious such knowledge as an architect can derive from observation is enough. Going through the trades in the specification according to their order we begin with excavator. It is, I think, obvious that he would not improve himself in architecture by going to work in the trenches with pick, shovel and wheelbarrow.

Next comes bricklayer and waller. I once built a brick wall, but I do not know that I learned much from it, except that

bricklaying was not so easy as it looked, and that if it was hard to keep a true upright it was still harder to keep a true level. The bricklayer to whom I showed my wall when it was done could only say that he thought it strong but very ugly. I do not know that I should advise any of you to follow my example.

Carpentry and joinery are more within the reach of every one, and a course of training at the bench may safely be recommended to all who have to do with building as supremely useful.

I need not go through all the trades, but masonry brings us near to the very centre of architecture. To be a practical mason would not in my opinion be so useful an accomplishment for an architect as skill in joiner's work. The ordinary problems of stonecutting can, I think, be understood without actually handling the chisel and mallet. But masonry, as I have said, melts insensibly into sculpture, and it is not always easy to say where masonry ends and sculpture begins. What will you do when you come to the carving of your building, as, of course, come you must in a building of any importance? If you only care for quantity and not for quality, you can, of course, leave it, as many do, to the carver, and simply get an estimate and leave him to do his best, which in that case may be also his worst. But you will not, I am sure, if you are in earnest, be content with so perfunctory and vicarious a way of bestowing on your work its principal adornment. You will have your own notions of the scale, the character and the finish of your carved work; you will feel that the outline of your sculptured capitals is as important as the profile of your mouldings; that the play of light and shade in your foliated string-course or your enriched frieze was an important element in your design; you will desire for your sculpture an historical character, illustrating the purpose and circumstances of your building; and above all you will feel that the same feeling which you have impressed on the purely architectural part of your design must be carried into the sculptured decoration, or the unity of the effect will be marred. You must impress yourself on that as you have done on the rest.

How are you to do this? You may spend hours standing over the sculptor or watching him model what is afterwards to be carved, and tire both him and yourself by suggestions and counter-suggestions which perhaps end in mere mediocrity and dulness, because though both of you want something different you do not want the same thing and are unable to explain your meaning to one another. But if you were able to finger the clay yourself you could realise to yourself your own intention and explain it to him perfectly, and in this way you would succeed in getting what you want as you can in no other.

Every architectural student, therefore, ought to learn to model. He will find it of the greatest service to him in his future career, not only in enabling him to explain his meaning to those artists who will collaborate with him, but also in fixing and correcting his own loose ideas of sculptured decoration and helping him to secure for it that character which will correspond to his intention. If he goes on to carve, so much the better; for my part I should like to see the callings of sculptor and architect rolled into one.

As to the other crafts, time forbids me to speak more at length. Every man, be he artist or not, should, as with the ancient Jews, be taught some handicraft; and to us architects such an accomplishment would naturally be doubly useful. We cannot expect that an architect should have actual manual experience of them all; still less can we require, with the Greek writer, that he should have mastered them all. But we have a right to demand that he shall by actual observation acquaint himself with the methods and difficulties of them all, not from books but from the workmen, not in the library but in the workshop. Let him never make a design without knowing how it will be carried out, and if in doubt let him go with it to the workshop, the building shed, or the forge; let him consult the men who are to make it, and then correct or alter his design to suit the difficulties of material and workmanship. In this way we may expect to infuse a new life into our architecture and to awake it from its torpor. The knowledge you will acquire in this way will not be of a kind to be tested by examination, or to enable you to win prizes and scholarships, but you may feel assured it will be the means of making you better artists individually, and of advancing the art of your country as a whole.

Mr. Owen Fleming, who proposed a vote of thanks, said he had listened with great interest to Mr. Jackson's thoughtful investigations of the difficulties and obstacles which beset architects in their practice. Regarding a knowledge of the intricacies of the crafts a few architects had been self-sacrificing enough to learn to understand them, but this was a task many others did not care to undertake, although, undoubtedly, the work of those who had thus schooled themselves would compare favourably with the work of men who neglected crafts. After speaking at some length on the *régime* of the Association in the past, Mr. Fleming said that one of the means to become successful in the examinations was by the aid of the knowledge

of the arts and crafts, and in furtherance of this workshops should be incorporated in their new building.

Mr. Hampden W. Pratt seconded the vote. He was thankful for what had been explained in the paper so clearly and moderately. Although it had been suggested that architects should be trained in every art, yet Mr. Jackson urged that if this was not possible architects ought at least to be taught one handicraft. Students who had taken up masonry and carpentry would fulfil all that was expected of them. It would often do a man a great deal of good to follow one craft, whereas if he followed more than one the divided knowledge would have bad results. Their modelling class was very good, and it showed a start had been made in the right direction, and everyone was in favour of being intimately acquainted with the handicrafts, as we have no competent workmen nowadays who could design the details; the only thing is for the architect to make the drawings.

Mr. C. H. Brodie thought architectural students would know more of their work if they were forced to visit buildings whilst in course of erection, the same as engineers were bound to inspect great works whilst they were in operation. Architects should therefore go out on the building when the different trades were working and get explanations to any question they might raise. For an architect to do his duty he must visit workshops.

Mr. Banister Fletcher also spoke, and the Chairman summarised the discussion and put the vote of thanks.

It was announced that Mr. Hugh Stannus would read a paper at the next meeting on the "Classic Cornice."

## RATING OF ENGINEERING UNDERTAKINGS.\*

THE question of the assessment for rating purposes of our great engineering undertakings, such as railways, canals, gas and water works, is necessarily one of vital interest to all engineers connected, either directly or indirectly, with the management of such concerns and the importance to them of some knowledge, however limited, of the method in which undertakings under their control are assessed, has suggested to the author that a paper upon the subject—which will, it is hoped, give scope for an interesting discussion—may not be entirely without interest.

It is common knowledge that no town of any importance is without its railway system and its gas and water supply, but the extent to which these undertakings contribute to local taxation is comparatively little known; and still less, that in some rural parishes, through which the trunk line of a large railway company passes, it sometimes happens that the proprietors of the railway pay as much to the parochial authorities as the total of the other ratepayers combined. This, on the face of it, appears to be an injustice, and more especially so when one considers that the acreage of land in the parish occupied by the company is infinitesimal compared with that occupied by the other contributors to the rates. Primarily, however, it must be borne in mind that the fundamental principle upon which every hereditament is rated, whatever that hereditament may be, is its rental value, the last definition of the term "gross value" by statute being "The annual rent which a tenant might reasonably be expected, taking one year with another, to pay for a hereditament if the tenant undertook to pay all usual tenant's rates and taxes and tithe commutation rent-charge (if any), and if the landlord undertook to bear the cost of the repairs, insurance and other expenses (if any) necessary to maintain the property in a state to command that rent." At the first glance it would appear to be inequitable that the railway company should contribute out of all proportion, as regards the area of its property, to the other ratepayers, and that one piece of land adjacent to another should vary so largely in value for assessment purposes; and one might almost be led to hastily conclude that the hard-and-fast rule that trade profits should not be rated had been broken. Upon consideration, however, this will be proved to be an erroneous conclusion, and it will be seen that the old axiom of a property being worth what it will fetch may be well applied here, for in the event of the railway company not possessing the fee-simple in the land, they would be willing to give a large rent, and it is upon this hypothesis their assessment is fixed.

The method of ascertaining the hypothetical rental value is one of great moment to every parishioner, for, theoretically, as the total rateable value of a parish increases, the rate in the £ diminishes; and consequently the small ratepayer possesses an obvious advantage in a company occupying land in the same parish in which his own property is situated. At the same time, it must not be lost sight of that the law is framed with the prime object of equality, and although a company is, perhaps, better able to pay more than its just share of the local burdens

as compared with an individual occupier of property, it was not the intention of the Legislature that it should be called upon to do so, and any policy initiated by the local authorities tending in that direction cannot be too vehemently denounced. On the other hand, a wealthy company has a decided advantage over a poor parish, in so far as it has greater facilities for legal proceedings, and in many cases the dividends to its shareholders are held in higher esteem than the obligatory duty which it is under to each ratepayer in every parish in which it is a taxpayer. This, however, is somewhat a digression as regards the direct subject of this paper; but the excuse must be the importance of the point, which could not be altogether overlooked.

The facts, firstly, that trade profits are not rateable, and secondly, that the rateable value of such undertakings as canal or railway companies is calculated upon their receipts and expenses as going concerns, is to the casual observer irreconcilable; but upon carefully studying the matter, the equity and fairness of both of these rating rules are fully demonstrated.

When the assessment of any hereditament is being considered (such hereditament being occupied by the owners) the object, as has been previously stated, is to find the rent which a hypothetical tenant could afford to pay a hypothetical landlord for a similar occupancy, and the first question which must arise is as to how much of the property would belong to the landlord and how much to the tenant—for it must not be forgotten that, with the exception of a few incorporeal hereditaments, it is the land itself which is liable to the rate, and its value *quod* land only is increased by the uses to which it is put. In the case of a large company (whose system extends possibly from the south to the north of England), when the published accounts are submitted for the purpose of making a valuation of a small isolated parish, say, for instance, in Yorkshire—for these accounts are practically the only data upon which an equitable assessment can be determined—the situation can be appreciated when we remember that only this one portion of the whole undertaking is to be assessed, and that for this purpose it has to be assumed that it is possible for a tenant to enter into possession of it, consequently the rent which he could afford to pay for this part alone has to be estimated from the accounts.

Now, it would be a comparatively easy task for a properly constituted body to determine the rental value of the whole system of the London and North-Western Railway, for example, and then to apportion the rateable value to the several parishes claiming a share, according to the length of line in each parish. But such a principle of assessment has been set aside by the courts, and justly so, as it must be patent that an occupier of property in some rural parish should not have the advantage of a contribution to the common fund of another ratepayer, owing to the fact of such ratepayer being a company which has property extending through many parishes, and that the average rateable value per mile of the whole of their system allows a higher assessment to be placed upon the property in this rural parish than would otherwise be the case. The same injustice is suffered in those parishes where, through this equalisation, the company's assessment was not as high as it should be. One illustration will make this point clear. Take a mile of railway at Paddington and another at Penzance. Obviously, a landlord could command a higher rent at Paddington than at Penzance. This being the case, why should the ratepayers of Paddington pay more, because one of their number pays to Penzance taxes which are justly payable to Paddington? The principle, then, to be borne in mind when assessing these extensive undertakings is that they shall be assessed in each parish according to the value of the occupation in that parish.

The method of arriving at the rateable value of a hereditament on the receipts and expenses principle is briefly as follows:—The gross receipts have first of all to be obtained, and from these have to be deducted:—

1. The working expenses. 2. Management expenses.
3. Government charges (if any). 4. Rates and taxes. 5. Rental value of dead works.

The result obtained is the profit accruing from the undertaking. The hypothetical tenant who has, it is assumed, sunk capital in the concern would then require a return by way of interest, &c., for his money, and a sum to represent this amount has now to be deducted from the gross profits to satisfy his claims, the residue being the amount he could afford and would be willing to pay the hypothetical landlord for his occupation—in other words, the gross value of the property. From this sum the usual statutable deductions are made, viz. those for maintenance, &c., and the result will be the rateable value, upon which basis most of the taxes are paid.

This, then, is the principle which is adopted when assessing railways, canals, gas and water companies, &c., and its application, although varying in some slight details as the character of the particular hereditament varies, may be taken to be practically similar in every case.

Dealing more particularly with railway companies, the question of parochial receipts and the working and management

\* A paper by Mr. P. Michael Faraday, read at the meeting of the Society of Engineers on April 5, 1897.

expenses may be passed over, as they chiefly resolve themselves into a matter of book-keeping; although it is not for one moment suggested that a keen appreciation of the purpose for which these amounts are taken from the accounts should be lacking in any one whose duty it is to compile them. The result, if this knowledge be wanting, would probably be useless; but time will not permit of the author going thoroughly into the details of the various sums which would be included under these headings.

Perhaps the most important item in the valuation of a railway company is the hypothetical tenant's capital. It may not be widely known that, as a general principle underlying railway legislation, a railway company has not exclusive use of the right of way over its railroad, and that any private individual has the privilege of running his own engine and carriages over the line of way constructed by the company on payment of tolls, in the same way that a barge-owner is allowed to carry freight over a canal by paying to the canal company certain tolls for the usage thereof. It follows, therefore, that in dealing with these enormous undertakings it has to be assumed that there are two capitals employed, one belonging to the hypothetical landlord and the other to the hypothetical tenant. As for the engines, carriages, &c., rent is not paid—land only being rateable; it is clear that the hypothetical rent or gross value is paid only for the privilege of using the line of way. The land occupied by the running lines, therefore, constitutes the hypothetical landlord's property, and the return which he is assumed to receive for his capital sunk in this property is the gross value, or, as it is sometimes termed, the landlord's share. Consequently, we have to deal only with the interest, &c., derived from the hypothetical landlord's capital, and have no occasion to ascertain the capitalised amount of this interest.

With the tenant's capital the situation is different. Although, as has already been pointed out, a hypothetical tenant is assumed to exist, the capital which he would require cannot be assumed; this figure has to be worked out upon the basis of the occupation—that is to say, each hereditament has to be dealt with as it exists at the time the valuation is made, the uses to which it is then put, and no other considerations whatever must enter into the calculation. The constituents of a tenant's capital of a railway company would consist chiefly of the rolling stock, conveyances at the various termini, horses, &c., tenant's stores, furniture and fittings at the stations, all non-rateable machinery and tools; in addition to which he would require a certain sum of money as working capital. The task of ascertaining the tenant's capital for a railway of any importance is necessarily one of great difficulty, and a question might arise as to whether the various items should be taken at their prime or first cost, or if they are to be estimated at their present value. The answer to this point is that they are to be taken at their actual value, above or below their cost when first purchased by the company; because an incoming tenant would say, "What rent can I afford to pay upon taking over this property? It is obvious that the amount I can pay as rent must depend upon the deductions to be made from the gross earnings in respect of profits, interest, &c., due upon my capital invested therein, and I must, therefore, calculate these profits on the amount of capital actually required to be expended on the stock; not on what may have been the value of stock at another time, or in other hands." The present cost, therefore, is what has to be ascertained, and when this amount has been fixed, the percentage to be allowed the hypothetical tenant, as his share of the profits, &c., of the undertaking, must be determined. Upon this point probably more cases are contested than upon any others which arise in connection with a rating appeal.

There are three distinct sums to which he is entitled:—

- (1) Interest on his capital. (2) Trade profits from the concern.
- (3) A sum to be set aside for risks and casualties.

Custom, to a large extent, is responsible for certain amounts, and there is nothing more difficult to set aside than an unwritten law which is more or less universally adopted. Five per cent. is usually allowed for interest, 10 per cent. for trade profits, and 2 and 1½ per cent. for risks and casualties.

With regard to the amount for interest, it is a well-known fact that nothing like 5 per cent. can be obtained at the present day for money invested in trust funds, and, undoubtedly, the rate of interest for money in the market should influence the rate of interest to be allowed a hypothetical tenant who, having invested his capital, is allowed, by law, a certain sum in the form of interest, putting aside altogether the question of trade profits which he also derives from the concern. The interest allowed on the tenant's capital, therefore, is, as a rule, 17½ per cent., but a lower rate is sometimes contended for.

The stations, sidings, &c., of a railway company (and these are termed "dead works") are assessed upon a different principle to that of the running lines, and, when making a valuation of the line, a deduction should be made from the gross receipts to allow for the rent which a tenant would have to pay for the use of the stations over the whole of the system. Of course, the gross value of the stations is the rent which the railway company would be willing to pay for them under the

statutory terms. The amount of money taken at a station does not affect the rateable value of it, for stations are largely for the convenience of the company to facilitate the collecting of their tolls, the money being earned over the whole route by which the passengers and goods are conveyed. To estimate the rental value of a station it is necessary to ascertain its cost of construction; and by taking a percentage upon this and adding a percentage upon the value of the site a figure representing the gross value is arrived at. Signals and sidings are included in the valuation of the station, as, theoretically speaking, if a train ran from one terminus to another and there were no intermediate stations, no signals would be required. They are only erected because of the stoppages which take place and the many stations situated on the route of a great trunk line. The case, however, with regard to signals at a junction is different, as these are included in the valuation of the line.

The foregoing deductions having been made from the gross receipts, the gross value of the undertaking is arrived at, and from this has to be deducted a sum to allow for the maintenance and renewal of the permanent way. It would be very difficult to determine the sum of money necessary for the maintenance of any one mile of railway. Cases could be cited without number, but we should be no nearer fixing an amount which might be laid down as an invariable rule. A railway company could probably give the actual expenses incurred on any particular section, as the method they have of keeping their accounts would allow of this, but the sum for renewal is so involved with that of maintenance that it would be almost impossible to separate the two; indeed, no one could say from an examination of the accounts where maintenance left off and where renewal began. Repair and renewal, in point of fact, go on simultaneously, and when making a valuation of a railway company an inclusive figure to cover both items is very often estimated. In ascertaining this amount it must be borne in mind that, although the parochial system is to be adopted, there are certain expenses connected with the maintenance of tunnels and viaducts, and notwithstanding that they are incurred in the parish for which the valuation is made, they must not be charged wholly to that parish, as the tunnel or viaduct, as the case may be, is contributing to the earnings everywhere, and without either or both the traffic on each side of the particular parish could have no existence. It must be apparent that the figure (unless given by the railway company) is an estimate, and consequently the amount of train mileage must have considerable bearing upon the question, as where the traffic is heavy the expenses will be greater than where it is light, although not necessarily by any means in the same proportion.

This deduction having been made, the rateable value in the parish is arrived at, but it must be obvious that in a great number of cases it will be found impossible to adopt this principle, for it is a *sine quâ non* that to arrive at a successful result the amount of parochial receipts must exceed the amount of the deductions, or otherwise there would be no rateable value. On the other hand, every branch of a railway company's line must of necessity have some value to the railway company, for if this were not the case an application would be made for permission to close such part. Consequently we have the following position:—On the system of most of our large railway companies there is usually to be found one main or trunk line with several branches; many of these branches are worked at a loss, but they are the means of bringing traffic to the main line as feeders, and as such they are material sources of wealth to the company. In the event of the whole system of the railway company being contained in one parish, the difficulty of the assessment of such would be easily surmounted, but the parochial principle having to be adopted, owing to its running through many parishes, the local receipts and expenses are those only which can be taken into account. It follows, therefore, that in certain parishes railway companies may be in the possession of property which contributes nothing to the local rates, for although there is undoubted value to the present occupier, the question which really determines the assessment is, What is the value of this property *per se* to a tenant if it were to let? The answer to this of course must be nil, for it would be impossible to find a tenant for a property of a trading concern the expenses of which exceeded its receipts. The railway company, however, does not gain from this cause, as it has to pay additional rates elsewhere. Should it so happen that in one parish there are two portions of line, one making a profit and the other working at a loss, the profits made upon the one line must first of all be devoted to paying off the deficit upon the other, after which the apportionment for the rateable value should be made.

With regard to the rating of canals, great similarity exists between this class of property and that last dealt with. They have both the same common object, although the business of carrying passengers by canal has largely diminished since the introduction of railways. Formerly land over which a canal passed was rated as if it were not applied to the purposes of a canal, but as if it had remained in the hands of individual owners and was used for ordinary agricultural purposes. Canals

are now rated upon the principle of their receipts and expenses, this principle having previously been explained in the case of railway companies, but the buildings and reservoirs necessary for the proper working are assessed upon a percentage of their structural cost, these corresponding to the stations of a railway company.

When making a valuation of a gas or a water company the same principle is adopted, but there is one difficulty less to contend with than in the case of a railway, for with regard to the live mains the parochial principle is only applied to a gas or water undertaking as far as the receipts are concerned. A valuation in these cases is made of the whole concern, and after the division is made between the dead works and the live works the rateable value is apportioned to the several parishes in which the hereditament is situated, in the same proportion as the rateable value of the whole bears to the gross receipts of the entire undertaking.

The great point of attack and the difficulties of defence in these cases, as in all others where the principle of receipts and expenses is adopted, is the tenant's capital. Now a water company has a great advantage over a gas company; it has statutory rights to collect its rates in advance, and it generally avails itself of this privilege. Obviously, therefore, an incoming tenant of a water company would require less capital than an incoming tenant of a gas company, for a gas company must manufacture its gas and deliver it to the consumer before it receives any revenue, with the small exception of that derived from the sale of the residual products; whilst, on the other hand, a water company receives its income prior to delivering its water to the consumer. This must have a considerable bearing upon the question of the capital necessary to carry on the undertaking.

The question of the dead mains or live mains is one of considerable importance, both to the parochial authorities and to the company whose assessment is under consideration. A gas or water company may have its works situated some distance away from where its produce is consumed, and the carrying mains are very often situated in parishes in which there are no receipts. Again, in other parishes there are mains which are directly tapped for the convenience of ratepayers and others which are only carrying gas or water, as the case may be, to some distant point of the district which they supply. The division between these two classes of mains must be accurately made, for whilst the directly productive mains are assessed upon the receipts and expenses principle, the unproductive or carrying mains are assessed upon a percentage of their structural cost. It would be impossible to lay down a rule that would be applicable in every case (indeed probably every case would vary according to the size of the district supplied by the company), but it may be interesting and useful to note that in the appeal of the Gas Light and Coke Company in so many parishes against the quinquennial valuation of 1890, the system adopted by the court was that of treating all mains of 24 inches and upward as being unproductive or dead mains.

The gasholders and retorts necessary for the carrying on of a gas undertaking and the reservoirs and pumping stations of a water company are rateable at their rental value, and this value is derived from their structural cost. It has been sought to exempt gasholders and retorts as coming under the category of tenant's tools, but the fallacy of this contention was at once pointed out by the court.

In conclusion, the author may appropriately quote the words of one of our well-known judges, who aptly said, "It is impossible to be mathematically accurate, but it is my effort only to lay down a general rule, and the applying of it must be left, not only to the experience and acuteness, but also to the good sense, good faith and candour of the parties concerned, whose interest will be found in the end to be best consulted by this mode of dealing."

### NEW EMPIRE THEATRE, GLASGOW.

THE new theatre which has been built by the Glasgow Empire Palace Company, to take the place of the old Gaiety Theatre, is now open to the public. It is situated in Sauchiehall Street and West Nile Street, the company, of which Mr. H. E. Moss is managing director, having acquired and demolished the old theatre and adjoining property to make room for the new structure, which consists of a large block of buildings forming a very striking feature in that part of the city. The plans were prepared by the well-known theatrical architect, Mr. Frank Matcham, who has succeeded in producing a palace of varieties which in point of elegance will compare very favourably with any similar place of entertainment in the kingdom. The elevations are of bold Classic design, faced with Dumfriesshire freestone of a light red colour. The front to Sauchiehall Street contains four handsome shops, with show-rooms above, and in the centre are the entrances to the principal parts of the theatre. Over these entrances is a large bay window, filled in with coloured glass, and the elevation is

continued up with pilaster mouldings and carved figures, surmounted by a large panel containing the words "Empire Palace Theatre," with art panels over. The whole is flanked by projecting bays continued up to the roof and finishing with minarets. Over the centre façade is a large domed roof, and in front a gas flambeau, which gives a brilliant light at night. In front of the theatre is erected a handsome glass and iron shelter, finished in cream and gold. At each side of the principal entrance are the early door entrances to the pit stalls, circles, &c. Four shops are contained in the West Nile Street front, with the entrance to the pit in the centre of the block. This is a fine lofty entrance, with a circular, richly decorated ceiling, the walls being covered with tiles. An ingenious arrangement for the pay office is here carried out without barriers, each person being conducted singly to the pay office by means of doors hung to open and close automatically, the exit doors being always left clear in case of need. The same pay office takes the money for the gallery, the entrance to which is in Sauchiehall Lane, and a similar arrangement is carried out to that described for the pit. The building is admirably arranged as regards exits, there being two separate exits from each floor of the house, and in some cases more. The galleries are constructed on the cantilever principle, and are set back considerably over one another, giving a fine view of the house from all parts. The ground floor consists of six rows of gold plush, richly upholstered arm-chairs, with a similarly finished settee dividing these fauteuils from the pit, which is comfortably seated and upholstered with velvet, the floors being covered with linoleum. There is a wide gangway at the rear of these seats, and behind is a raised promenade, from which an excellent view of the stage can be obtained. The grand circle contains six rows of tip-up chairs similar to the stalls, and there is a railed-off gangway with a raised foyer in the rear, this containing columns and pilasters of faience work beautifully decorated and furnished with lounge and chairs, and covered with rich Wilton carpet. French casement windows open from the centre on an outer smoking balcony overlooking West Nile Street, which, fitted up with ferns and plants, will make a very comfortable smoking lounge during the summer evenings. The balcony over the grand circle is comfortably seated, and furnished with a promenade and raised refreshment saloon at the back. At the sides of the grand circle are four private boxes, so arranged that an excellent view of the stage is obtained. There are also four proscenium boxes, with entrance to the fauteuils. The gallery is a particularly good one, every seat affording a clear view of the stage. An innovation is introduced in the arrangement of the sliding roof. In other theatres this is placed over the centre of the auditorium ceiling, but in this case Mr. Matcham has altered the position and placed it over the gallery. The result is that the ventilation is improved, and the impure air is instantly carried away by the opening of the roof, which is worked with the greatest ease from the stage. The gallery is provided with refreshment-rooms situated on a level with the centre seats, and easily accessible from all parts. The pit saloon is in the basement, and is a large apartment with two wide staircases, the walls of which, like those of the pit, are lined with encaustic tiles. The floor of the grand vestibule, which is entered from Sauchiehall Street, is in mosaics, and the walls are covered with faience-work. The inner vestibule containing the pay office is a very handsome apartment, the walls being painted a warm green shade, and the ceilings richly decorated with raised plaster-work. All the woodwork in these parts is of polished walnut. To the left is the gentlemen's cloak-room, and at the side a wide stone staircase leads to the crush-room, and thence into the upper circle. On the right the vestibule doors lead to the grand marble staircase, from which is the entrance to one side of the walls, a subway under the front of the stage conducting the visitor to the opposite side of the stalls, and thus avoiding the inconvenience of having to pass those seated. The grand staircase leads to a very luxurious lounge, with a rich coved ceiling, in the centre of which is a large opening surrounded by an open balcony. This lounge is continued up to the entrance to the grand circle lobby, and is lighted by a large glass roof light, and well ventilated, the whole forming a fine smoking promenade. To the left of this lounge is the large saloon, which has a handsome domed ceiling, and is elegantly fitted up and decorated. The decorations of the auditorium have been artistically carried out from Mr. Matcham's designs in Louis Quinze; but special treatment has been bestowed on this work by the architect not only in the raised work, but also in the painting, and the whole theatre decorations represent Dresden china. The ceiling is not of the usual disc shape, but is formed of curves with three centre panels artistically painted. The proscenium is circular-headed, and is filled in with open scrollwork. In the centre is a full-size figure raising aloft a harp, and the effect is very artistic. The front of the galleries is treated to correspond, and special treatment has been given to the entrance for the private boxes and stalls. Over the artists' entry on each side of the proscenium are groups of figures

representing music and dancing, and above these are large standards in imitation china, containing electric lights. The box and tableau curtains are of a light gold colour, and the whole interior, when illuminated by the electric light, presents a brilliant appearance. The stage is a large one, and is fitted up with all the latest and most improved machinery. Large dressing-rooms are placed in conjunction, heated by hot water and lighted by electricity. Retiring-rooms are provided, and the comfort of the artists has been studied in every way. The building will accommodate altogether 2,158 persons, divided in the following manner:—Stalls, 156; pit, 655; dress circle, 220; upper circle, 327; gallery, 750; private boxes, 50. The total expenditure on the reconstruction of the theatre will be about 30,000*l*.

#### ARCHITECTURAL ASSOCIATION OF IRELAND.

THE first annual conversazione of the Architectural Association of Ireland has been held in the Royal Hibernian Academy House, Lower Abbey Street. As a social reunion the conversazione was a great success, and should be regarded as a promising augury for the future of the Association, which is only of recent formation, but is already thriving to a remarkable degree considering its infancy. The handsome halls of the Royal Hibernian Academy were placed by the council of that body at the disposal of the Architectural Association. The guests were received by Mr. R. C. Orpen, president, and the committee of the Association. All the visitors were thoughtfully provided by the Association with catalogues of the exhibition, which enabled them to enjoy the excellent collection of pictures with advantage.

#### LEEDS NEW MEAT MARKET.

A CONSIDERABLE portion of a cleared insanitary area in the city has (says the *Leeds Mercury*) been devoted as a site for a market, abattoir, &c., and there is now being completed on the ground perhaps the finest structure of the kind in the country. The old meat market had an area of 607 square yards; the new one covers 12,243 square yards. The architectural features of the new structure are handsome. The style is a modification of the Spanish Renaissance. From the wholesale yard inclined planes lead to the cattle lairs. In this way space has been economised. The wholesale slaughter-houses, over which the lairs are situated, afford accommodation for twenty wholesale butchers. Two men will be able to work in each division, and there is additional space for the slaughter of sheep and calves. The wholesale meat market, having Bradford Street on the one side and Cheapside on the other, is 365 feet long and 88 feet wide. Its ground floor forms one apartment, with a single span roof 64 feet from floor to ridge. The windows and eaves are so arranged that abundance of light is secured, whilst the direct rays of the sun are excluded. The whole of the building is provided with electric lighting, the engines and dynamos being located in a portion of the basement. Another portion of the basement is fitted up as a cold store, with chilled and freezing-rooms. Access to the basement is obtained by subways, broad enough to admit carts. The meat market has eighty "stances," or butchers' stalls. Lifts and overhead travelling gear facilitate the conveyance of the meat to and from the cold store. Two slaughtering halls are provided for the retail butchers. That for beasts and sheep is 240 feet long; the other for pigs 96 feet long. The lairs for the beasts and sheep occupy the upper storey; those for pigs are on the ground floor, pigs having an objection to going upstairs. Ample supplies of cold and hot water are provided, and operations in the pig hall will be facilitated by travelling gear, scalding tanks, &c. Twenty-six beasts, besides sheep, may be killed at a time, and even double the number should occasion require it. Close to these halls are pens for the animals about to be slaughtered. The charge for slaughtering is so much per animal. In another part of the building is a hide, skin, and fat house, and near this are the slaughter-men's mess-rooms. Overhead are the triperies. There is likewise accommodation for the slaughtering of condemned animals, including special lairs and provision for destroying the carcasses by fire. A tower, rising to a height of 100 feet, contains five large tanks, so that, independent of the ordinary supply, water may always be at command. The rain-water from the roofs is also collected for the cleansing of the yards and like purposes. Carts will be loaded and unloaded under cover, so that the traffic in the thoroughfares outside may not be obstructed. Internal operations will be materially expedited by a system of small trucks running on tram-lines. The blood from the slaughtering-halls will be collected and sold, and when the albumen has been extracted from it the remains will go for manure.

The structure, the total cost of which, including the site, is estimated at 90,000*l*., also includes a two-storey range of offices,

and in a short time the trade will be in possession of one of the most extensive and commodious markets of the kind in the provinces.

#### GLASGOW MASONIC HALL.

THE Masonic temple which has been built at 100 West Regent Street to accommodate the Glasgow brethren of the craft stands on the north side of the thoroughfare. Two buildings have been erected, the one fronting the street, and the other on the back portion of the ground. The former has been almost entirely arranged in suites of offices, the rents of which will furnish a considerable annual revenue. The other one is devoted entirely to Masonic purposes. The designs were prepared by Mr. J. L. Cowan, who has adopted a free treatment of the English Renaissance style of architecture. The building is four storeys in height. The basement is occupied by reception, cloak and ladies' rooms, with a purveyor's kitchen, as well as a machinery room containing the appliances for mechanical heating and ventilation. On the street level a commodious hall has been constructed, 64 feet long by 38 feet wide. There is a dado panelled in stained-wood 9 feet high, and above the walls are treated somewhat elaborately, with capitals between the windows, which run round three sides. The lights are semicircular headed, and are filled with stained-glass on which are displayed the arms of Grand Lodge, the Provincial Grand Lodge, the arms of the city and various masonic symbols. The hall is comfortably seated for 400 persons, and there is a pneumatic organ. On the next floor there is a commodious lodge-room, 45 feet by 26 feet, and a large adjacent room, with committee, smoking and other rooms. The lodge-room is treated simply and severely in the old Greek style. There is a lesser lodge-room above, 30 feet by 24 feet, and there are a storeroom and caretaker's house of three apartments on the top floor. The cost of the buildings was 11,500*l*., which together with 4,000*l*. paid for the site and the money spent on decoration, brings the total expenditure up to about 16,000*l*.

#### The Building Trades Exhibition.

SIR,—We beg to tender you our sincere thanks for your notice of our stand at the Building Trades Exhibition in your issue of March 26; but we notice that you have divided your description of our exhibits, the first portion being under the heading "Sutton & Co." and the second part "Green & Co.," whilst between them has been put a notice of Messrs. Outram & Co.'s exhibits. We have nothing to do with Messrs. Outram & Co., but the goods described under the heading "Green & Co." being shown on our stand and manufactured by us for the patentee (Mr. Green), we thought it well to call attention to this.—Yours faithfully,

SUTTON & CO.

#### GENERAL.

Mr. H. Wilde, president of the Manchester Literary and Philosophical Society, has given 5,500*l*. to the French Academy of Sciences in order to found an annual prize of 4,000 francs, which is to be given to the author of a discovery in astronomy, physics, chemistry, mineralogy or mechanics, or a book on those subjects, as an expression of the donor's gratitude to French science.

M. Gérôme, the French painter, is to exhibit another experiment in sculpture at this year's Salon, viz. an equestrian figure of General Bonaparte in an Egyptian costume.

Two Paintings were stolen a week ago from the National Gallery, Budapest. One is Murillo's *St. Joseph*, the other Van der Neer's *Riverside Town*. Copies of the pictures, carefully prepared, were substituted by the thieves.

The Drama Section of the Victorian Era Exhibition will contain a room devoted to theatre architecture, in which drawings will be hung to show the development of theatre-building during the last sixty years, including such technical improvements as refer to iron construction, lighting, ventilation and stage appliances. Mr. Edwin O. Sachs has undertaken the arrangement of the room, and most of the theatre architects, who have been invited by him to send loans, have promised to help with working drawings, perspectives, or photographs of their work.

# The Architect.

## THE WEEK.

THE judgment which Mr. Justice NORTH delivered in *COLERIDGE v. LESLIE & Co., Limited*, on Tuesday must give occasion for much anxiety to many builders and manufacturers in London. The plaintiff owns a house in Roland Gardens, a terrace which branches off the Old Brompton Road. That part of the Metropolis was, until a comparatively late period, occupied as market gardens or as fields. There could be no objection raised when a firm of builders a quarter of a century ago opened works on ground that stood near the site afterwards selected for the plaintiff's house. The usual machinery was employed until 1894, when the works became the property of the defendants. During the eight years' occupancy of his house the plaintiff never complained of any excessive noise or vibration to the defendants' predecessors in title. In 1896 the defendants set up a gas engine to work saws and planes, and it was alleged by the plaintiff that the noise and vibration began daily at 6.30 A.M., and continued, practically without cessation, till 5.30 P.M. and sometimes until 8 P.M., and were distinctly heard and felt in every part of the plaintiff's house, and that they constituted a serious nuisance to the plaintiff and his family. On account of the noise and vibration, the ordinary and reasonable comfort of the plaintiff and his family, as occupiers of his house, had been wholly destroyed, and he and the members of his family, and particularly his wife, had in consequence suffered seriously in health. The plaintiff alleged also that the continuance of the nuisance caused by the noise and vibration would render his house unfit for use as a private residence, and that its value would be seriously depreciated. The plaintiff claimed an injunction to restrain the defendants, their servants, &c. from working their gas-engines at their works, and from otherwise carrying on their business in such a manner as by the noise and vibration occasioned thereby to cause a nuisance to the plaintiff. It was the defendants' contention that the continuous user gave them a right to use their premises in the same way as was exercised since 1871. Mr. Justice NORTH, however, granted the injunction on the ground that the plaintiff had established there was a nuisance. The importance of the case is manifest. There was no doubt an introduction of a new engine in 1896, but it is inevitable that machinery will wear out and must be replaced. It is always difficult to compare the relative effects of old and new engines on the ears of people who live in the neighbourhood, but more effective machinery apparently brings the risk of an injunction.

SOME of the county archæological societies have arranged for photographic illustrations as records of objects which have interest on various accounts. A proposal to establish a national photographic record collection has been brought before the trustees of the British Museum by Sir BENJAMIN STONE, M.P., who has offered a series of a hundred platinotype views of Westminster Abbey as a commencement. He has been informed that the trustees are in full agreement that such a record survey collection, if carefully and systematically brought together, cannot fail to be of the greatest value and interest both to the present and to future generations, and they are most willing to take charge of the photographs which from time to time may be deposited with them. The scheme, however, it is said, can only be satisfactorily carried out under the immediate direction of an organising committee, that would serve as a centre of reference for societies and persons willing to contribute photographs, and at the same time be in correspondence with the officers of the Museum. The trustees hope that the formation of such a committee will be arranged at an early date, and so confident are they of a general recognition of the value of the proposal that they have no doubt that a very representative body of gentlemen may without much difficulty be found ready to undertake the immediate direction of the work. The trustees will be happy to render through their officers all the assistance in their power. It is proposed to form a preliminary committee to organise

the work and to invite to act upon it representatives of the Royal Society, the Society of Antiquaries, the Royal Photographic Society, the Royal Institute of British Architects, the Royal Archæological Institute, the Royal Geographical Society, the Trustees of the British Museum and others. The council of the Warwickshire Photographic Survey have promised a first contribution of 100 pictures of that county.

MR. JAMES DREDGE, the Honorary Executive Commissioner of the British section of the Brussels International Exhibition, writes to us to say that he is in a position to state positively what are the actual prospects of success in the section. Commencing with a court of 30,000 square feet, the applications from manufacturers have rendered it necessary, on several occasions, to obtain more space from the exhibition authorities, until to-day the commercial courts of the British section occupy no less than 70,000 square feet, besides some thousands of feet in the machinery hall, and a series of fine arts courts, which it is confidently anticipated will be in all respects worthily representative of British contemporary art. It may therefore now be stated that, as regards its extent, the British section at the Brussels Exhibition will leave little to be desired. It will be much smaller than the French section, which has had the advantage of a very large Government grant; on the other hand, it will be far more extensive than that of any other foreign country. The Industrial Courts may not contain exhibits of a very novel or monumental character, but they will be filled with contributions from exhibitors of high standing, and distinctly representative in their various branches of industry. Therefore, as regards quality of exhibits, as well as extent of space occupied, this country will be well represented. This result could not have been obtained without united and continuous efforts on the part of the British Commission, and its president, Sir ALBERT KAYE ROLLIT, and especially of the executive committee; while the undoubted success of the Fine Arts Section is due to Sir EDWARD POYNTER and the members of his sub-committee, who have laboured under very difficult and discouraging conditions.

A MEETING of the Society of Antiquaries of Scotland was held on Monday, when Mr. J. BALFOUR PAUL, Lyon King-of-Arms, read some notes on old Scottish measures, based chiefly on the Acts and the notices in the "Regium Majestatem," with special reference to the Inverkeithing standard ellwand, which was exhibited by permission of the magistrates and Town Council of Inverkeithing. The subject of Scottish weights and measures still waits a competent exponent who will take the trouble to follow out an obscure and somewhat abstruse inquiry. The earliest measures mentioned as having been in use in Britain were computed by natural standards, as thumbs, palms or hands, feet, &c. In England the thumb had disappeared as a measure before the reign of ÆTHELSTAN, and the barleycorn had taken its place. The palm or hand survives to our own day as a standard measurement for the height of horses. The nail is still a cloth measure, though the earliest standard of cloth measurement, when cloth or wadmal was a currency instead of coinage in the North of Europe, was the ell, from which came our yard. In an assyse of King DAVID I. of Scotland, as noted in the "Regium Majestatem," we are told that the Scottish ell "aught to conteyn" in length 37 inches." By the same authority the inch was to be computed on the average of the thumbs of three men—a big man, a little man and a man of middle stature, or else by the total length of three barleycorns "but the tails." From the fourteenth century downwards many statutes were enacted by the Scottish Parliament for the regulation of the weights and measures of the country, and in 1503 all the burghs were ordered to send to Edinburgh and get a sealed standard of all the weights and measures. The Inverkeithing standard ellwand is a thin bar of brass or bell-metal, clamped between two rods of iron by rivets, and having a portion cut out of one side of the brass bar exactly 37 inches in length. On the brass bar at one end is the inscription in black letter, "Willelmus Carmichel," and the date 1500. Another standard ellwand of wood, also from Inverkeithing, with the initials "W. N." and "D. G.," for Dean of Guild, was exhibited.

## THE EASTERN CRISIS AND ARCHÆOLOGY.

THE majority of newspaper readers are bored by the apparently uneventful course of the broil between Turkey and Greece. But there are two classes of people who would be eager to see it going on as slowly for an unlimited time. They are the dealers in antiquities and those who purchase from them. Both have numerous representatives. In Turkey as well as Greece the unauthorised disposal of ancient remains is a serious crime. A farmer or landowner is not allowed to begin explorations on his property for the purpose of finding the smallest object unless he has obtained the sanction of the representative of Government in his district. To make sure that not a particle of marble, bronze, or terra-cotta escapes official notice, a duly appointed overseer is to be present during all the operations, who makes a record of everything that turns up. In practice, however, so many formalities are only observed in excavations on an immense scale, which could not by any ingenuity be concealed. Foreigners alone respect them. The ordinary Greek, whether in his own country or in a part of the Turkish Empire, contrives to make many archæological experiments without giving the least trouble to a Government officer. His illicit operations are not always calculated to produce results which are entirely satisfactory to archæologists. In his haste there may be much destruction committed. Statues are often broken in the course of the clumsy operations; nay, they are sometimes broken purposely in order to facilitate removal. If a work happens to be in fragments a part only is withdrawn, for a head or an arm, when finely modelled, can always command a price. The beautiful Tanagra figurines, which were accepted as a revelation of a variety of Greek art that was more interesting to the general public than figures of heroic mould, afford examples of what can be done in defiance of law. The ancient necropolis was almost entirely looted before the authorities of Bœotia became aware of the discovery. It is true a great many officials may have witnessed such an outbreak of industry, but as DICKENS'S Commissioner PORTAGE said on an occasion when delays could not be tolerated:—"There has been no written correspondence, no documents have passed, no memoranda have been made, no minutes have been made, no entries and counter-entries appear in the official muniments." When the preliminaries were regularly gone through, and Government could intervene in a majestic manner, the ground presented only countless small fragments which testified to the expedition employed, while many European museums and private collections were enriched by several most charming additions. The gain was counterbalanced by the difficulty of comprehending under what conditions the figurines were discovered. The treasure-hunters were too busy to trouble themselves with making any records of the character of the tombs, and as a consequence, although the world is enriched by many beautiful objects, there is not much gain to archæology. We cannot tell when the terra-cotta figures were produced, or why so many of them should be representative of youth. If the explorations had been conducted by skilled archæologists—and on such an occasion all the civilised world should have a share in the work—we should then become better acquainted with ancient life than we are ever likely to be. There would also have been less destruction, for through the greed of the diggers probably as many objects were destroyed as were rescued. The Tanagra case is an example on a large scale of the weakness of Greek law to control efforts by which gain is likely to arise. If the authorities failed on that occasion in grappling with a crowd of people, how can they be expected to deal with operations which are carried out by one or two individuals in darkness and at a longer distance from a military post? The power to control the people is, moreover, not likely to be increased during such a crisis as is now being evolved.

Greece is a poor country, and we cannot expect that the market value could be paid by the Government for any treasure trove which it is considered desirable to keep in the country. Suppose a farmer is fortunate enough when ploughing to knock against a work of art of the importance of the *Venus* found in the Isle of Melos, and that, respecting the law, he announces his discovery. A Government

officer or one of the archæological societies will then assess its value. The amount is sure to be no more than a fractional part of the sum which one of the numerous dealers who have foreign clients is willing to give. If, however, the finder is tempted by the larger sum and declines the national offer, he will have to surrender to the Treasury one half of the money he receives. He is therefore prompted by his own interest to be silent about his good fortune. As he knows that the statue will be confiscated if his negotiations with outsiders are discovered he is the more anxious to be secretive. The dealers will, of course, save him from every kind of vexation if he will allow them to manage the business. In consequence, no department of the Greek Government can speak with certainty about the extent of the researches after ancient examples, and at a time like the present there is a likelihood the operations will become more general.

It may be doubted whether new operations are necessary. If next week it were announced that the performers in the "Concert of Europe" were prepared to purchase at a liberal price all examples of ancient sculpture which were brought under notice within a period not exceeding a month, the world would be amazed with the expedition with which supply corresponded with demand. There would be no time to produce fabrications. All the works would be genuine examples, and the cause of the promptitude of their appearance is that they were already discovered but were again concealed in the earth awaiting a favourable opportunity. The main difficulty which prevents a stock of antique sculpture from coming into the market is one of transport. The roads in Greece are not favourable to expeditious transport, and in the tedious journey between an inland farm and a seaport there is always a chance that contraband exports will be discovered and seized. If the restrictions were removed London, Paris and New York would be glutted with antiquity. By law every Greek is supposed to furnish the authorities with an inventory of all examples of ancient art which he possesses in order that from time to time his collection can be tested. But that regulation has become a dead letter, for it is observed by no more than a few people, and it is certainly unknown to those country folks who unearth and rebury works of art.

The dealers, who cannot entirely escape scrutiny, also contrive to delude the official inspectors. There are few, if any, experts belonging to the great museums of Europe or America who would accept a dealer's account of the discovery of a work in marble, bronze or terra-cotta. In order to escape detection, works which are found in a particular district are said to have come from places which are remote from it. To be truthful would often lead to the knowledge of many a fertile field, which would not be advantageous to the initiated. One result is that the works of various schools are confounded, and thus it happens that the worst places for the training of specialists are the shops of Greek dealers. In no department of art is ordinary connoisseurship of so little use as in that which is concerned with Greek archæology.

It is not a good sign in any country when a large number of the inhabitants are in a sort of tacit conspiracy against the law. Disloyalty easily spreads. At present the Greeks who respect the edicts against the exportation of antiques are those who have never known what it is to be tempted. Some would believe in the use of obstacles to free trade in sculpture if they found that the retention of ancient examples in any way helped to make the country more prosperous. But every shrewd Greek knows that he has gained more sympathy from the world from the Parthenon marbles finding a refuge in Bloomsbury than if they were left on the Acropolis of Athens. As long as he finds he can profit by the reputation of the ancient sculptors he does not care to incur expense to preserve their works. He would like to have numerous examples of sculpture because he knows they can always be exchanged for money, but he prefers to allow to strangers the privilege of erecting any buildings which are necessary to keep them from mouldering. The scandalous neglect of the *Hermes* of PRAXITELES, which was allowed to remain lying on the damp ground after its discovery, is by itself sufficient evidence of the peculiar way in which the Greeks show their reverence for master-

pieces. If it had been carried off to Berlin, every Greek could pose as a martyr for ever, and from a business point of view that enjoyment would be preferable to the possession of an imperfect figure.

If, therefore, during the present year a larger number of examples of sculpture should be derived from Greece we hope we shall not have to witness such fictitious revolts as were popular among sentimental people when the reliefs of the Parthenon were rescued by Lord ELGIN. Experience has shown that he was a friend of Greece in saving that country from the possibility of committing acts of vandalism. The country is also exposed to dangers from without, and it is as well that works of art which have ceased to inspire the Greeks with any desire of imitation should be kept in safety in Paris, Berlin, or London, or at least until the time arrives when there is a possibility of a new era for art in Greece.

What we have said about the Greeks is more applicable to the Turks. They cannot claim to have any interest in the works of the ancient Greeks or the neighbouring people. Excellent as the Turkish notion of a civilised state may be, for its realisation, there is no need of enclosing statuary in a museum which is to be hermetically closed. The Ottoman can be happy enough although he does not gaze on cold marble. But his pride will not allow him to dispense with objects for which he can have no use. We grant it is more satisfactory to know that a statue is in the museum of Constantinople than if it were on its way to a limekiln. But the proper place for a work of art is wherever it is likely to find most admirers, and that is not within the region where the SULTAN rules.

#### SALISBURY CATHEDRAL.—IV.

AT the close of the article on Salisbury Cathedral in last week's number we referred to the restoration which was directed by the late Sir GILBERT SCOTT. His work recalls the very different sort of "restoration" which was perpetrated by JAMES WYATT. There can be no question about the destruction of ancient work, and WYATT appears for once to have considered that restoration and removal were equivalent words. His fame has been sullied by the constant recalling of the operations he performed at Salisbury, and we suppose he is never likely to be considered as more than a vandal. If judged by a later standard of the limits of restoration he was undoubtedly a wrong-doer, for he deprived the world of many objects which may have merited preservation. But is it equitable to judge any man by a higher standard than what was recognised by his contemporaries? If we observe the wise rule of putting ourselves in WYATT's place and consider what was becoming by the help of eighteenth-century beliefs, we may find that his conduct, however lamentable in its results, was not quite so wicked as it is declared to be by lovers of Mediæval architecture.

In the first place, we should remember that WYATT belonged, like all the architects of his time, to the Classic school. He had studied Greek and Roman temples, and from them had, like other men, derived a theory of architecture which he believed was the only one which was based on true principles. In our time a sort of comprehensive view is taken of the numerous varieties of architecture. We see the Time-spirit adopting one form, and then, as if grown tired of its repetition, substituting another. But in WYATT's days people could not attain that sort of belief, or if it arose it was set aside as dangerous because it led to a variety of latitudinarianism, of which the effects could not be measured, they were so far-reaching. WYATT was in reality less narrow-minded in his beliefs than most of the architects of the time, for he considered it was his duty to have drawings prepared of several Gothic buildings at great expense, in order to discover if the style were based on principles which could be defined, and that concession signified much. His own attempts to design Gothic buildings were in consequence less absurd than many in that age. But drawings, however numerous, could not convince him that it was unnecessary for an architectural work to have unity. That was the foundation of his artistic creed.

At Salisbury WYATT saw a building which allowed him to infer that in its original condition it came nearer to a Classic temple in unity than any other Mediæval church

in England. It had been added to and otherwise altered, but he perceived that if the excrescences could be removed the primitive unity would be restored. Moreover, some of the additions had weakened the cathedral. The much-lamented Hungerford chantry was an instance, for in order to find space for it one of the buttresses had to be removed, and the main building was thereby endangered. The very numerous monuments were mainly of insignificant people whose reputation had not got beyond the county boundary, and WYATT was, we imagine, obeying not only the orders of the Dean and Chapter but the wishes of the public when he removed them from positions where they were too prominent. The majority of visitors generally believe it would have been an advantage if WYATT had carried off some more of those which have survived.

There is another aspect under which we should consider WYATT's restoration. Was it not likely to have been dictated by the cathedral authorities on doctrinal or devotional grounds, and, as a faithful son of the Church, was not the architect bound to obey? Twenty years ago the Bishop of CARLISLE, who was an able and broad-minded man of science as well as a churchman, was not afraid to declare that the sacrifice of antiquity was occasionally demanded out of respect for orthodoxy. In a sermon before the church building society of his diocese he said:—"I think we are bound to remember that we are Christians and churchmen first, and everything else afterwards. Our primary question concerning any church must be, Is this building adapted to the worship of the Church of England as I find it set forth in the Book of Common Prayer? Can I worship in it suitably and fully as a member of the Church of England? And if the church in question be so constructed or so deformed that this worship be not possible, then I think that conservatism is out of place. I cannot look upon churches as mere monuments of the dead. They are this, but they are much more, they are places of worship for living souls."

Now at Salisbury, among the trophies of "restoration" were not only monuments of the dead but temples of the dead. What, for example, was the Hungerford Chapel but a building dedicated to the remains of one family, and for which one of the walls of the lady chapel was destroyed? A sketch which has survived shows that the ornamentation was vulgar but ostentatious. The Beauchamp Chapel was a similar tribute to family pride, and women used at one time to assemble in it carrying torches, a practice that was not prescribed by any law of the Church. The chapels were useless except as curiosities, and they helped to make a sort of museum of the cathedral. It should also be remembered that the representatives of the BEAUCHAMP and HUNGERFORD families consented to the alteration. The effort to bring Salisbury Cathedral into keeping with reformed ritual was not commenced by the Dean under whose instructions WYATT acted. Bishop JEWEL long before had endeavoured to get rid of the stained-glass windows which contained subjects of which he could not approve, and from time to time it was considered necessary to offer similar sacrifices to reform. When WYATT was called in it had been decided to make a more thorough clearance. He was inspired by a love of architecture; the cathedral clergy wished to show affection to the reformed doctrines: both were therefore enemies of the excrescences which were introduced after ELIAS OF Dereham's time.

The removal of the screen which is charged to WYATT alone is likely to have been dictated by the authorities. By that act the lady chapel was shortened. But what purpose can a lady chapel serve in a modern cathedral? In a few places it may be used as a morning chapel, but generally it appears as a sort of store-room in which benches are piled until they are required for extraordinary purposes. We know of one estimable clergyman's wife who holds the theory that the lady chapel was constructed for the conferences of dames in her position, with a Mrs. PROUDIE as president, and neither her husband nor her friends have been able to convince her that it was intended for any other function. It is commonly said that the change, which practically amounted to a suppression of the lady chapel, was inspired by WYATT alone, who was eager to have the full length of the cathedral opened out to the first glance of a visitor, but it is more likely the clergy wished to demonstrate that the days for lady chapels and mortuary chapels had

passed away. We do not approve of the transforming process as it was practised at Salisbury, but we believe that the whole responsibility for it should not rest on JAMES WYATT, for the clergy would never have handed over the cathedral to him for his operations or with the object of making it a more perfect example of architecture. There were other causes at work which were due to their influence, and of which the alterations were the results.

In whatever proportion we may measure out blame for the restoration, we cannot deny it was sweeping. The detached bell-tower, if not unique in England, was at least sufficiently uncommon to be worth preservation. The structure is supposed to have been demolished in order to allow of a view of the cathedral, to which it was an obstacle, but that theory is inadequate. Its rarity was likely to have been its chief defect in the eyes of the arbiters of taste at that time. It was also a rival to the fine tower of the cathedral, the uselessness of which as a belfry was suggested by it. But some of WYATT'S removals were less to be deplored. JOHN CARTER, for example, becomes sentimental over the withdrawal of a large number of iron bars which, in the chapter-house, stretched from the central cluster of columns to every angle. He had to admit they were a deformity, for their dark lines obstructed the curvature of the groins; but as they had existed for a century he would have them preserved. WYATT said they were of no constructive advantage, and could be removed with safety, and his judgment is confirmed by the stability of the chapter-house. But there are enthusiasts who would hold such obstructions as sacred things, although the only use of them was as evidence of the ignorance of the people who set up the bars, and who evidently could not understand how a vaulted roof was able to stand for three centuries without the aid of a smith. The anecdote should be enough to suggest that WYATT was not always at fault. The removal of the bars was an undoubted improvement, and it is not unlikely that the architect introduced many others. CARTER was, however, confident that there could be no defects in work so long as it was not executed in his own time. Because Sir CHRISTOPHER WREN and PRICE, the cathedral surveyor, alluded to some shortcomings in parts, "Give me the man," he exclaimed, "who, if he dare avow his predilection for an object, an object like this of Sarum's sacred walls, let him adhere to the cause he is disposed to maintain, without having the fear of being thought of a superstitious turn, or that his bias for the 'heathen school' modes of science is whispered to be wavering." According to that theory a building that is once admired must be always admired. There is to be no opportunity for the exercise of a more matured judgment on works of art, and the changes of opinion which are allowable in considering most things are to be suppressed when the subject is a Mediæval building. CARTER'S views were adopted by PUGIN, and it is mainly to the passionate attacks of the two that people came to consider JAMES WYATT as the destroyer of a building which strangers somehow consider to be the most perfect in England.

### LEAD WORK.\*

MY having been invited to read a paper on lead working is, I suppose, a consequence of my having some years ago made a little book on the subject, which I have to mention because the notes which follow will be very much in the nature of an appendix to it. A kind and very friendly reviewer remarked that the essay in question had apparently been put together from material in my hands at the time of writing. This was penetratingly true, and I confess I look on the present as an opportunity of stringing together the few further facts (not for the most part purposely sought for) which have come in my way, or have been noted in my reading.

The account of ancient lead working could be much amplified, but I only propose to refer to the Roman coffins of this material to inquire how far they were of English lead and made in this country. These Roman coffins, I believe, fall into two main groups—the first and earliest (I think) found in south-east England and north-west France, and the other in Syria. The chief characteristic of the English examples seemed to be the use of the scallop shell in their decoration.

In an article in volume ix. of the Kent Archæological

Society, several Roman coffins found at Bexhill are described. One of these was ornamented with little Medusa heads and pairs of lions *affronté*. The absence of the scallop shell is remarked upon, and I cannot see anything which divides these off from the northern French examples, so that I am now inclined to look on all these as of English make.

I pointed out a small square vessel in the museum at Lewes as being of Saxon workmanship, but thought that it might be a font. I now find from its resemblance to another box found at Folkestone that it is more probably a relic casket. That found at Folkestone was ornamented with a network of lines formed of little beads. A portion of another lead relic casket has been found at Lyminge. A book cover in lead, with an inscription from *Elfric's Homilies* in runes, is another pretty example of Saxon workmanship.

As I have suggested was the case in the Roman Age, so also in the early Middle Ages the art of working in lead was an especially English industry. When about 1090 the roofs of Coutances Cathedral in Normandy had been destroyed by lightning, Geoffrey, the bishop, sent to England and called Brisenetus the plumber to make afresh the leadwork of the roofs and tower, and to replace a gilt weather-cock. (*Memoires de la Société des Antiquaires de la Normandie*, 1824, p. 155.)

There are in England about thirty fonts, or rather font basins, of lead; they are mostly of cylindrical shape, are beautifully ornamented, and in the main belong to the end of the twelfth and the thirteenth centuries. The question of French or English crops up again with regard to the fonts. The beautiful font at Brookland, in Romney Marsh, is, I have come to the conclusion, of French work, as it is in many respects identical with a font at St. Evroult, between Le Mans and Falaise.

In regard to the English examples, I have been informed that the font at Clewer, which is usually given in the list of lead fonts, is not of that material. That at Wansford, in Northamptonshire, is also said to be of stone. According to the *Antiquary*, there is a font at Oxenhall, Gloucestershire. In the Gloucester Museum there is, I am told, a lead font, and also a small vessel ornamented with reliefs of the instruments of the Passion. The font at Ashover, in Derbyshire (described sometimes—by myself amongst the number—as of stone with lead figures) has the basin entirely of lead; it is surrounded by twenty figures of apostles. All the figures were repetitions of two models, such was the economy of means by which these old works of art were produced.

De Caumont has described several French fonts of lead of the twelfth century. In the *Abécédaire* he gives some figures of the font of St. Evroult de Montford (Orne). Between four figures (which although repeats of the same model stand for the four Evangelists) are placed a double row of little arcaded panels occupied by the labours of the months, each being surmounted by one of the signs of the Zodiac. They are not placed in order, and are repeated three or even four times. "The matrices which made the mould each carried two months." De Caumont remarks on the panels being evidently a set of stock patterns to be used for different purposes, and notices the resemblance to the Brookland font, which must have been made in the same shop.

In the fourteenth century and later, lead fonts continued to be made in France. De Caumont illustrates a fine octagonal example at Mesnil-Mauger. In the Museum at Rouen one of three examples is as late as Francis I., another is of fifteenth-century work with a long inscription in three lines running all round it, the third is of the twelfth century. In the same museum is a beautiful abbey lavatory of lead similar to if not the same as that illustrated by Viollet le Duc as of bronze, also some fine finials.

The lead font of Maintz is probably the largest and most carefully wrought lead font existing; it is in the form of a melon-shaped cup, ornamented with figure subjects of Christ, the Virgin, St. Martin and the Apostles. It was cast 1328, and must be 5 or 6 feet in diameter. This is a cathedral font, all the others belong to small village churches.

Methods of water-supply were much more advanced in the Middle Ages than we are likely to suppose. "Water leaders" seem to have been separate from plumbers, as we find both mentioned amongst the York crafts who took part in the mystery plays. A water-leader was at work at the Palace of Westminster early in the reign of Henry III., and a conduit (doubtless the well-known canopied fountain in New Palace Yard) is mentioned in connection with the work. These fountains or conduits are the typical feature of Mediæval water-supply. Four such fountains are shown in the elaborate plans for laying on the water to Christ Church, Canterbury, shown in the twelfth-century plan. Here basins in one or two stages stand under lead-covered roofs supported on pillars, just like those which to-day may be found in the courts of the Greek monasteries of Mount Athos. Such central fountains in the courts, with here and there a draw off to a lavatory or kitchen, must have been the general method of distributing water in monasteries and the great houses. The water was first col-

\* A paper read by Mr. W. R. Lethaby in the Applied Art Section of the Society of Arts on March 30.

lected into a basin or reservoir, and then carried to one of these conduits in lead pipes." The streets of London were extensively supplied with such fountains at the end of the thirteenth century, and notices of the several conduits may be found in the pages of Stow. The canopied fountain in Trinity Quad, Cambridge, follows this traditional form, and probably now best represents some of these old conduits; others were solid erections.

Some interesting facts in regard to the water-supply of Hampton Court may be found in Law's history of the palace. At Nonsuch a large water tower formed part of the palace; it contained an immense cistern of lead, from which pipes supplied the whole house with water. In the gardens were several fountains, but these were principally of marble.

At Windsor, in the middle of the sixteenth century, but before the Gothic tradition had entirely lapsed, a great fountain, mostly of lead, was erected in 1555, when water was conveyed to the Castle from Blackmore Park, five miles away. The accounts of this work exist, from which we see that John Puncherdon, "Plummer," had charge of the work. A pipe was brought to the centre of the great upper court, "and there the water plentifully did rise 13 foot high." A reservoir was formed from which water was distributed to every part of the building, and a fountain "of curious workmanship" was made in the court. It consisted of a great basin with a canopy "gorgeously decorated with heraldic ornaments, coloured and gilt." In the centre a great Tudor dragon spouted the water into the basin.

In the accounts we have such items as these:—

Plumbers working the cistern and laying pipes. Carpenters making the great mould in the plumbry. Carvers carving the carthowages (cartouches) and scouchions for the fountain in wood and stone. Founders casting patterns in metal to garnish the cistern and top of the fountain. Carvers carving scouchions in wainscott to make patterns for the moulds of the scouchions, and badges to garnish the cistern and top of the fountain. Plumbers soldering arms about the fountain, and leading the lavatory about it. For carving six Beasts Royal, viz. an eagle, 6 feet long; a lion, 5 feet 11 inches; the antelope, 5 feet 6 inches; greyhound, 5 feet 5 inches; the griffith, 5 feet 4 inches; the dragon with his base, 13 feet 4 inches. (The Royal beasts were the Tudor badges.) To John Puncherdon, sergeant plumber, and Henry Deacon for finishing the garnishing of the fountain in great as was agreed between the Lord Treasurer and them, 60*l*. [For workmanship only.] To Nicholas Lyzard, sergeant painter, for painting and gilding the great vane with the king's and queen's arms, with a great crown. Also for painting, priming, stopping, gilding and varnishing a great lion and eagle holding up the said vane, first primed with soden oil, secondly with red lead and soden oil, then stopped with oils and red lead, then primed twice and wrought three times in colours, and so gilt with fine gold in oil, and so varnished. Also for painting in the same way the beasts, arms, freezes and cornices, 57*l*.

Lead cisterns in the kitchens of the palace at Westminster are mentioned as early as 1250. I know of none of Gothic workmanship still in existence. One of the finest of the later ones is at Nottingham Castle; it is ornamented with coats-of-arms. In the court off the south side of the cloister at Lincoln Cathedral there is a nicely decorated circular tub receiving the water from a down pipe, probably seventeenth-century work.

Old lead was cast for use on the spot by the plumbers. Accounts run "for founding and laying" so many fother of lead. The price for this in London in the thirteenth century for workmanship only (casting and laying) was 5*s*. a fother.

There are several interesting points about the laying of lead on plain roofs. At Exeter, for instance, the sheets do not run up the slope parallel to the gable ends, but incline to them at an angle. At Beauvais the sheets are laid horizontally about 10 feet long, the rolls being that distance apart, and intermediate support being given by clips. The early lead roofs I have examined have been laid on oak battens very thin and light, say 5 inches wide by half an inch, with a space of 2 inches or so between them. The rolls were always formed without wooden cores. These roofs of cathedrals were sometimes decorated by painted patterns. At Troyes, I am told, the roof was diapered over with golden flames.

How general and gorgeous was this decoration of leadwork in France may be judged from the fact that Rabelais makes the slated roof of the Abbey of Thelema to have a broad band of lead at the ridge with little gilt figures and animals, the down pipes being painted in diagonal stripes of gold and azure. Tinning was the favourite method of surface decoration for lead in France. There are not many existing instances of this work in England. At Hatfield some of the pipeheads have patterns of tinning which, the plumber there told me, showed evidence in some cases of being applied through a cut pattern like a stencil. Tinning also occurs, I believe, on the Knole pipeheads. Pierced work is best cut with mallet and chisels.

The *flèches*, or wood lead-covered spires which so often surmounted the roofs of French cathedrals, were usually so splendid with gilding and bright colours that they must have looked like large pieces of enamelled goldsmith's work. On the east end of the roof of Rheims stands the Angel *flèche* (remade about 1500); it is a lead-covered turret, about 60 feet

high. Round its supports stand eight images of lead, all gilt, and traces of painting and gilding are visible all over the lead-work. The rolls were gilt, and the surfaces chevroned in red and another colour. On its apex stands the angel which gives the *flèche* its name; it is of copper and turns to the wind. On the apex of the south transept gable is an ancient figure of a Sagittarius of gilt lead, which seems to discharge an arrow towards the court of the archbishop's palace, where a bronze fawn used to mark the point of its aim.

In the East lead-covered domes are frequently found entirely gilded all over. Travellers in Persia frequently mention the gilded domes at Koum and Ispahan. Early travellers' accounts make it clear that the dome over the Sacred Rock at Jerusalem was gilt, but the material was here, I believe, copper.

Tavernier writes that at Delhi there was a mosque, "the dome of which was entirely covered with lead, and so thoroughly well gilt that some indeed believe the whole is of massive gold." In Russia the domes of the churches all over the country are gilt or brightly painted.

It appears from a paper printed by the late Dr. Sparrow Simpson that when it was proposed to cover the dome of St. Paul's with copper, it was argued that copper "would soon be black and look ugly, so that the people would by no means be pleased with it." It was urged in reply that the "looks" of lead should not be set against the "duration" of copper, which also would be 600 tons lighter; lead, however, was chosen. John Roberts (plumber) estimated for lead 2,500*l*. Davis & Co. (coppersmiths) for copper 3,050*l*. It is interesting to note that copper even then went black, as it still does to our frequent disappointment. This blackness appears sometimes only an intermediate stage to the turning to the desired green, but sometimes I fancy the green never comes, at least in London.

The quantity of leadwork made use of in the Middle Ages in England was enormous; there seems to have been nothing like lead. I have before spoken of the typical London spire as being covered with lead. We find in inventories of St. Paul's how much it was used for small objects like holy-water basins, and even candlesticks. At the end of the Gothic period it was also greatly used in domestic and semi-domestic buildings, especially in London. Under Bread Street Ward, Stow describes "the most beautiful frame of fair houses and shops that be within the walls of London, or elsewhere in England, commonly called Goldsmith's Row . . . built by Thomas Wood, goldsmith, one of the sheriffs of London, in 1491. It containeth ten fair dwelling-houses and fourteen shops built four stories high; beautified towards the street with the goldsmiths' arms and the likeness of woodmen (in memory of his name) riding on monstrous beasts, all of which are richly painted over and gilt. The said front was again new painted and gilt over in the year 1594." This gaily illuminated leadwork was especially made use of in the fantastic tabernacle roofs which surmounted the octagonal turrets and bays so much in vogue in the Tudor period. We have only one or two little turret roofs left at Hampton Court to represent what were often tall and ornate structures painted and gilt like the houses just described or the great fountain at Windsor. From the prints of Richmond, Greenwich, Hampton Court and Nonsuch Palaces we are given some idea of the fantastic beauty of this work if we paint and gilt it in our imaginations. The descriptions of Nonsuch speak of it as "battlemented," with frames of wood covered with lead and supported with strong bars of iron, "which battlements are a great grace and special ornament to the building."

Numerous big houses in London would follow the same fashion, and almost every hall had one or two of those turret *louvres* of which that on Barnard's Inn Hall is the best existing specimen. In 1481, William Hariot, draper, gave 40*l*. to the making of the two "*louvres*" of the Guildhall. Stow also tells us that Sir Thomas Lovell, who built the gateway of Lincoln's Inn, "caused the Lacy's arms to be cast and wrought in lead on the *louvre* of the hall."

The spire of Old St. Paul's was burnt, as is well known, in the reign of Elizabeth, a hundred years before the great fire. Dugdale gives a view of the cathedral, showing a tall Renaissance steeple, which he appears to think was the original, for after describing that he adds, "A perfect representation of all which as it then stood I have here exhibited." The meaning of the Renaissance spire seems to be explained by a large drawing now in the possession of the Society of Antiquaries, when taken together with what Stow relates. It appears that the old spire was burnt in June 1561. Stow says:—"After this mischance the queen directed letters to the mayor willing him to take order for the speedy repairing of the same (the roofs and spire). The work was put in hand the same year, and the roofs completed before 1566. Concerning the steeple (continues Stow), divers models were devised and made, but little else was done, through whose default God knoweth. It was said that the money appointed for the new building of the steeple was collected."

The drawing at the Antiquaries is a large and very carefully detailed design, lettered, "New spire for St. Paul's in place

of that destroyed by lightning." On the design of the structure itself appears the date 1562. The engraving in Dugdale is a most careful rendering of this design put into perspective, and must represent one of the models prepared for the spire after the fire; the Antiquaries' drawing either being the original design or a copy of the same model.

The isolated belfry at Salisbury was an extremely beautiful erection contemporary with the cathedral, and standing to the north of it, where its position is yet marked on the grass in dry summers. From some prints the great beauty of this structure may be judged: a broad stone tower was surmounted by the belfry proper of wood covered with lead.

At Worcester there was a similar isolated belfry called the clochium or leaden steeple. This also is said to have been built in the time of Henry III. The tower was octagonal, 61 feet in diameter and only 60 feet high. It was surmounted by a wooden spire 150 feet high, which was thus  $2\frac{1}{2}$  times as tall as the tower it stood on—an abnormal proportion to our eyes. "Being considered of no use it was taken down in 1647."

At Westminster Abbey another isolated belfry was built about 1245-50. This stood in the Little Sanctuary. Stow describes it as "a strong clochard of stone and timber covered with lead," containing the great bells rung at coronations, triumphs and funerals. Other lead spires in London beside those I have before mentioned were St. Michael's, Cornhill, St. Dunstan's in the East and St. Laurence Pountney.

The corner pinnacles of the great early fourteenth-century leaden spires at Lincoln still exist. Seen from the tops of the towers they appear large works in themselves. When at Lincoln about a year ago I was grieved to find that most of the unique lead parapet to the choir, of thirteenth-century work, had been renewed. In the stonemason's yard I found and measured a portion of the oak planks over which the lead had been dressed; the thickness was 4 inches, the height 1 foot 10 $\frac{1}{2}$  inches, made up of two planks doweled together. The six-foil figures were 1 foot 6 inches diameter and roughly cut into the planks.

Of smaller gutters and pipeheads there are said to be pieces of late Gothic gutter in Tennant Street, Derby; and a very pretty piece of Elizabethan gutter with a pipehead is in a back street at Winchester.

A portion of the fourteenth-century ridge of Exeter Cathedral may be seen in a case on the top floor of the Architectural Museum. Old prints of Holyrood show a beautiful ridge which used to surmount the hall or chapel. At intervals large crowned roses and thistles (I think, for I speak from memory) stood up along the sky-line; these, of course, were painted and gilded.

A very pretty old *flèche* still surmounts King's College Chapel, Old Aberdeen, decorated with patterns cast with the sheets, such as shields bearing pots of lilies, the initials C.R., crowns, thistles, &c. A cast statue surmounting a town pump and other leadwork in the city have been brought to my notice by Mr. Watt.

The account of the Windsor fountain gives earlier instances of the casting of large figures in lead than any I knew before. I could give a considerable list of late garden figures and vases, but I wish merely to refer to one or two. A pair have lately been added to the South Kensington Museum from a garden near Shrewsbury. At Powis Castle, in Wales, there is a large Pegasus which formed a fountain, and at Naworth Castle, I am told, there are several figures. I know of one in a London shop, and there is said to be another down an area. One of the latest instances of the use of lead for statues known to me is a figure of Napoleon I. set up on the Arc de Triomphe in 1809.

One of the most curious uses of the material has been brought to my notice by a friend travelling in Germany. The floor of a room in a castle had lead inlaid in the wood to form a pattern. It is described to me as like a central sun, with waving rays filling up the rest of the space, the work probably of the seventeenth century.

Of inscriptions, the prettiest I have found noticed are two round plates about 12 inches in diameter, found engraved with the epitaphs of two twelfth-century bishops at Mont St. Michel. These were engraved with patterns and inscriptions, and were placed in the coffins beneath the heads of the bishops, like nimbuses. In one of the cases in the chapter-house at Westminster is a plaster duplicate of a cast lead inscription in beautiful "black letter," found on the coffin of Henry VII. The extremely minute relief on the Wolfe monument at the Abbey is by Cunningham, said to be of "lead bronzed over," the work of Capizzoldi.

Over the entrance to the Master's Court in the Charterhouse is a lead panel having the arms of Sutton and dated 1611.

It is almost useless trying to put interesting workmanship into dull and poor materials. It must be allowed that modern sheet lead has a poor, mean, crushed millboard look, and its wretched colour puts it quite out of court as anything but a mere makeshift. Cast lead, on the contrary, has a beautiful surface; it is cast with the greatest ease with the most simple of appliances and does not blacken by exposure to the air as

milled lead does. I had been told that the beautiful whiteness of old leadwork was owing to the silver left in the old metal; but this is not the case, or only in a small degree. Modern cast lead does not blacken like the milled sheets. For gutters and flats cast lead alone should be used, if for practical reasons alone. For purposes like hot-water sinks (for which milled lead is almost useless) cast lead will be found to answer. It is said that milled lead was introduced into England about 1670. The plumbers of the time opposed its use, and said it could not be durable. The Milling Company replied by offering to keep milled lead of 7 lbs. a foot in repair for forty years for an insurance of  $\frac{1}{4}$  per cent. That, to me, seems saying very little for the material; it would have said little in the Middle Ages at least—then the forty years' view of things had not been invented.

When, some months since, some practical classes were instituted by the Technical Education Board of the County Council in Regent Street, I was allowed to get my friend Mr. Troup, who has devoted much personal practice to working in lead, to supervise a class for experimenting in casting and ornamenting lead. A small casting table was set up, and I must confess that I there saw the casting of lead for the first time. The same course has also demonstrated the extreme ease with which this beautiful material is bossed up and otherwise manipulated. I find to-day that practical plumbers will explain that the great objection to cast lead is the comparative difficulty with which it can be beaten up. If they would only try they would find how mistaken this view is.

#### EDINBURGH ARCHITECTURAL SOCIETY.

At a meeting of the Society held on the 9th inst., the president, Mr. J. A. Williamson, in the chair, Mr. W. J. Anderson, lecturer on architecture in the School of Art, Glasgow, delivered a lecture on "The Origin of Greek Architecture." Mr. Anderson, who opened his lecture with a very interesting historical sketch of Greece, described the influence of wood construction on the architectural works of the Mycenaean Age. The lecture was illustrated by a large number of limelight views. Mr. Anderson was accorded a hearty vote of thanks.

#### TESSERÆ.

##### Record Offices in London.

IN 1578 an office for keeping papers and records concerning matters of State and Council was established, and Dr. Thomas Wilson (who was then Master of Requests and afterwards became one of the secretaries of State) was appointed the keeper and registrar. Before this establishment was formed it is not surprising that numerous papers of great importance should have been entirely lost and others have fallen into the possession of private persons. Sir Robert Cotton, in the reign of James I., and Sir Joseph Williamson, in that of Charles II., were most assiduous and successful collectors of those scattered papers. The collections of the former now form a portion of the library of the British Museum. Sir Joseph Williamson placed his collections in the State Paper Office. Another mass of papers, consisting principally of letters addressed to Cardinal Wolsey and to Cromwell, Earl of Essex, remained in the custody of the crown; but, instead of being deposited in the proper place, found its way into the chapter-house at Westminster. The three great receptacles, therefore, of State papers, antecedent to the year 1540, and partially down to the year 1578, were the State Paper Office, the chapter-house and the Cottonian Library. In the reign of James I. considerable attention appears to have been paid to the office. At this period the papers, which had been hitherto kept in chests, were reduced into the form of a library, and the king assigned certain apartments in his palace of Whitehall for their reception. Wilson seems to have experienced difficulty in getting possession of some of those apartments, and has left a curious memorandum of the presents and douceurs which he deemed it prudent to give to the lord chamberlain and Lord Worcester and their servants, to obtain one room, which had been the larder of the lord privy seal. The part of the palace finally appropriated to this purpose was the tower over the gateway which connected the eastern and western parts of the edifice standing across the street now known by the name of Whitehall. The apartments are described by Tucker as consisting of two rooms, three closets and three turrets. Of these Wilson did not get entire possession till 1618. This tower fortunately escaped the conflagration which destroyed a great part of the palace on June 12, 1619. During the civil war the office suffered spoliation and afterwards was neglected. In 1705 a committee of the House of Lords was appointed to inquire into the method of keeping records and public papers.

in offices. In consequence of a report from that committee, compiled from a return made by Tucker, an address was presented to Queen Anne, in which it was stated that with the exception of the papers of three secretaries of State, viz. Sir Edward Nicholas, the Earl of Arlington and Sir Joseph Williamson, and those left by Sir Leoline Jenkins, few papers had been delivered into the office since the year 1670, and even those so delivered were not perfect and many deficiencies are particularised. The address observed also upon the deficiency of space and the inconvenience arising from many papers being kept in bundles, and recommended the repair and enlargement of the office, and that the papers should be sorted and digested and bound in volumes. After a reference to Sir Christopher Wren, it was determined that the upper floor of the lord chamberlain's lodgings at the Cockpit should be fitted up and appropriated to the State Paper Office. This work was accordingly done, and an apartment 80 feet long and 25 feet wide, which was known by the name of the Middle Treasury Gallery, was then added to the office. In this state it remained until the old gateway was pulled down, about 1750, when the contents were found to have greatly suffered from vermin and wet. The papers contained in the gallery, which was left standing, remained there; but the contents of the rest of the office were removed to an old house in Scotland Yard, where they remained and suffered still further injury from wet till 1819, when it became necessary to pull down the last-named house, and the papers were again removed to another old house in Great George Street.

### Sixteenth-Century Architects in England.

Amidst the stars of lesser magnitude that beamed among the contemporaries and immediate predecessors of Inigo Jones were Girolamo da Treviso, who, like Holbein, practised both painting and architecture—the latter as an artist and not as a builder; Richard Lea, an Englishman, somewhat later; and another, named John Thynne, who built Somerset House in the Strand in 1567, in a mixed style of Italian and Gothic architecture. John Shute, an English painter and architect, who flourished in the reign of Queen Elizabeth, was sent by the Duke of Northumberland, his noble patron, to study the art under the best masters in Italy. He published in 1563 a folio volume of the principles of architecture, as developed in the most celebrated monuments of antiquity. Milizia, in his lives of architects, mentions an Englishman of the name of Stickle, who flourished about 1596, as an excellent architect. Robert Adams, who practised architecture and engineering, was superintendent of the royal buildings to Queen Elizabeth, and wrote a description of the river Thames and of the best method of fortifying it against an enemy. In the same period flourished Theodore Havens, an architect, sculptor and painter, who affected grandeur on a small scale and was rich in Italian conceits. He designed Caius College, Cambridge, a fair specimen of the architecture of the age—pedantic, eccentric, affected and trifling. This college was founded by Dr. Caius, physician to Queens Mary and Elizabeth; and three of its gates are of curious, if not of elegant, designs, being amongst the first constructed after the Italian manner in England. The first is inscribed "Humilitas," and, as the Gate of Humility, is of low proportions; the second, which is loftier and embellished with a portico and emblematical figure, is dedicated to Virtue, and is inscribed "Virtutis. Io. Caius posuit Sapientiae," and conducts to Caius Court and the public schools; and the third, which is inscribed "Honoris," and is called the Gate of Honour, is of still larger dimensions, and decorated with the various orders of Roman architecture, overlaid with ornaments, in the style of the ecclesiastical monuments of the period. About the same time, Rodolph Simmons built Emanuel and Sidney-Sussex Colleges, Cambridge, and rebuilt the greater part of Trinity College in the same University.

### Figures in Landscapes.

The earliest landscape-painters sought to give their pictures interest by placing a group of persons in the foreground engaged in some suggestive occupation. Thus Claude filled up his pastorals with shepherds and with dances under trees, while Salvator Rosa peopled the gloomy caverns and dark chestnut woods he loved to paint with bandits and soldiers. Rubens, in the celebrated landscape of the Pitti Gallery at Florence, has painted the story of Ulysses landing after his shipwreck on the shores of Phæacia beneath the palaces and gardens of Alcinoüs. The storm is broken overhead; vast rain clouds rolling off remind us of the tempest that is gone. The figure of Ulysses on the shore suggests the fury of the sea from which he has escaped, while Nausicaa and her maidens seem to welcome him to fresh sunlight and repose. The correspondence between returning calm in nature and the escape of the hero from his perils on the sea produce a unity of conception that makes this picture a fine poem. Many of Turner's greatest works might be taken as examples of the same sympathy between the scene in nature and the fortunes of

some hero or historic personage. But the landscape-painter need not depend so immediately as in the cases we have cited upon human interest. He may indicate it even in a more subordinate degree. Perhaps the most generally attractive of Turner's pictures is *The Fighting Téméraire*. This painting teems with objects and associations that provoke the warmest sympathy, and yet the human life there represented is entirely in the background. The sun is setting over the sea, while the crescent moon stands cold and clear to eastward. Between the sunset and the moonlight a black steamer-tug is drawing an old ship of war to her last resting-place. The sun is going down and night is coming on, but the red beams of the evening fall upon the steamer, while the white rigging and gigantic hull of the veteran ship look spectral in the pale light of the moon. The pathos of this picture depends upon the sympathy which it excites in us for the vast, helpless man-of-war. Men have always felt a personal attachment to their ships. Argo was respected as a kind of goddess, and Catullus wrote a sonnet to his favourite skiff. Equally in modern times are battleships regarded as actual personalities by the men who fight in them.

### Influence of Architecture.

When the soul of the artist has entered into his work, he has made of it a work of art, and he speaks to the souls of others. Perhaps it is in architecture that we see most clearly the growth of the arts into art. Architecture stands between "the arts" and "art," and partakes of both. Practical utility is its first aim, but beauty is its second. The true architect thinks not only of the purpose of his work, but of its influence on the minds of those who see it. He makes it express not only a presiding purpose, but an inspiring thought. The difference between King's Cross railway station and Westminster Hall is just the difference between architecture as the art of building and architecture as art. In the one the architect has been only a builder, in the other he has been an artist. The one has thought only of his useful purpose—the other has lavished love, and therefore beauty, on his work. The one has built a most convenient place for passengers to come to and go from—the other has built a place for men and women to gather in. The one has made a roof that lets in the light and keeps out the rain—the other has made one into which thought can soar and where imagination is at home. And that is the true test of a building as a work of art. It does not obtrude its purpose. The Manchester Assize Courts do not remind you of judge and jury. The splendid halls at Liverpool and Leeds do not call up irresistible associations either of municipal politics or of music. Our Gothic cathedrals do not merely remind us of sacraments or of sermons. It is characteristic of all good buildings that, whatever your mood of mind, you feel at home in them. A sense of peace and satisfaction descends on you. An elevating influence enters into you. The outside world falls away to a distance, you are lifted above it sometimes even out of yourself. The spell of art is on you, and you linger in the place unwilling to break the charm. It is with a plunge you find yourself again among the bustle of the street; you seem to have awakened from a pleasing dream, and you would fain close your eyes and dream the dream again, and dream it always. You have had something of that enjoyment which beautiful natural scenery gives, but with the additional mysterious charm which the human element in it imparts to art. That human element is the especial characteristic of art. It is that in it which "finds us," as Coleridge says. The Great Soul which speaks through nature speaks only to an elect few—the human soul in art speaks home to all. And it is that human element which is the distinct addition that, in all its departments, art can make to nature.

### St. Ambrogio, Milan.

St. Ambrogio is the finest example of the early basilica type in northern Italy, the region where, after the fall of the Empire, sacred architecture first acquired a complete and intelligently organised style, partaking both of the Roman and Byzantine, whilst in certain features differing from both—the style which, in fact, continued dominant in the West from the fifth to the eleventh century, coextensively with the Latin church. St. Ambrogio shows that, up to this period at least, sacred architecture continued true to its high and proper aim, that seeks to embody in the material building a type of the spiritual Church, her discipline and mysteries, without which the essential character proper to the Christian temple is lost. The system of symbolism in early art, developed under the Longobards, and henceforth obtaining more and more in the sacred edifice, is presented in a very curious series among the outer details at St. Ambrogio (the portal and columns of the atrium), and here we see, besides the figures familiar in such mystic acceptance, birds and animals, also Adam and Eve, the centaur, emblematic either of the lower passions or the swift course of man's life; the syren, of sin and its dangers; also the pomegranate (perhaps its first appearance in a symbolic sense), to imply by its numerous seeds the abundant charity of the saints.

## NOTES AND COMMENTS.

THE next international congress on technical education will be opened in London on June 15, when the Duke of DEVONSHIRE, K.G., will deliver an address. The subjects discussed will relate to technical and commercial education. Each branch will be divided into two sections, viz. advanced instruction and secondary instruction. The elementary stages will not be considered. All papers will have to be sent to the Secretary of the Society of Arts not later than May 29. They may be written in French, German, or English. The congress will be held at the invitation of the Society of Arts and the Companies of Drapers, Fishmongers, Goldsmiths, Merchant Taylors, and Clothworkers.

ACCORDING to the report of the Berks Archæological Society, there has been progress during the past year in historical research and architectural study. Delegates of the Society attended the Annual Congress of Archæological Societies at Burlington House, when the following subjects were discussed:—(1) Parish Registers; (2) The Preservation of Ancient Monuments; (3) County Museums; (4) Catalogues of Portraits in the Possession of County Families; (5) The Study of Ground Plans of Churches; (6) County Bibliography. Some steps have been taken with regard to the photographic survey of the county of Berks. A camera club having been recently formed in connection with the University Extension College, the Secretary gave an address upon the subject, and it was unanimously agreed that a survey should be undertaken by the camera club and commenced during the forthcoming season. It was announced that Mr. W. RAVENSCROFT had presented the Society with a series of brass rubbings from Shottesbrooke Church, and that Dr. HURRY was preparing a plan of Reading Abbey for the Society, which would comprise an architectural description, with the correct dimensions of the various buildings, and an historical description of the chief events connected with them. The officers of the Society were re-elected at the annual meeting.

A SOCIETY has been founded for the purpose of reproducing by modern facsimile processes the works of ALBERT DÜRER and his school. It proposes to issue in the first instance a series of faithful copies of the engravings, woodcuts and drawings of these artists, and to include such paintings as have not been published in a satisfactory form, or are from some other reason inaccessible. A number of plates will also be devoted to illustrating the relations of German with Italian art during the fifteenth and sixteenth centuries. A portfolio will be issued annually containing from fifteen to twenty-five subjects, accompanied by text. The method of reproduction will in each case be that best adapted to render the special qualities of the original. It has been decided to limit the number of members to 250 subscribers of one guinea each. Mr. F. WHELEN is hon. treasurer.

THE Corporation of London have agreed to provide increased accommodation for students at the Guildhall School of Music. The principal (Mr. W. H. CUMMINGS) had informed the committee that additional class room had become an imperative necessity, and that if such provision were not made the growth and progress of the school would undoubtedly be seriously checked. Intending students could not be accepted either because the rooms were already occupied at the particular times they could make it convenient to attend for their lessons, or because they wished to join the class of some particular professor who was quite willing to give more time to the school, but for whom it was impossible to find a vacant teaching room. A large practice-room was absolutely indispensable for the practice of the choir and orchestra combined, which at present was impossible, for the practice of the full orchestra and for the operatic and dramatic classes. The plans for the expansion of the school on vacant land at the rear of the present building, belonging to the Corporation, make provision for a commodious orchestral saloon capable of seating 650 persons and the addition of twenty-seven new classrooms. The site to be occupied measures 72 feet by 51 feet, or an area of about 3,700 square feet, and the cost will be 20,500*l*. The Corporation will advance this amount

as a loan out of the City's cash at a moderate rate of interest; to be repaid in equal annual instalments in fifty years. The liability which will thus be incurred by the school, including the ground-rent of the new building (460*l*.) and additional expenses of staff, will amount to 1,500*l*. a year. To meet this increased liability the entrance fees and tuition fees will have to be increased.

THE following buildings have been visited on the past five Saturday afternoons by the students attending Professor GOURLAY'S classes in architecture and building construction at the Glasgow and West of Scotland Technical College. A new brick kiln of the Hoffman type at Seedhill, near Paisley; Mr. R. W. FORSYTH'S new warehouse, Renfield Street, Glasgow (Messrs. JOHN BURNET, SON & CAMPBELL, architects); Miss CRANSTON'S new restaurant, Buchanan Street (Mr. GEORGE WASHINGTON-BROWNE, architect, Edinburgh); Langside Road United Presbyterian Church (Mr. JOHN B. WILSON, architect); the new Art Galleries and Museum, Kelvingrove Park (Messrs. SIMPSON & MILNER-ALLEN, architects, London). There was a good attendance at all the visits.

IN Paris the Municipal Council appear to be always on the look out for new means of levying imposts. The last discovery is ingenious. It is proposed to subject the metal plaques which the insurance companies place on façades as evidence of protection to a duty. The theory adopted is that the plaques are projections, although only to an infinitesimal extent, and must, therefore, be made liable to extra payment. It was not anticipated there would be any resistance to the proposal. The companies, however, have adopted a very efficacious means of escape. They have removed the plaques, and by that simple stroke the Municipal Council are rendered powerless and left to discover another subject which will be less portable.

A CORRESPONDENT, who feels aggrieved by the election of a fire brigade officer in Dublin, writes as follows:—"I note your remarks in last week's issue anent the appointment of assistant superintendent of the fire brigade at Dublin. You say the Corporation acted wisely in compelling candidates to submit to a competitive examination. This is manifestly correct; but did they maintain their wisdom when, after the results of the examination, they balloted for the men (apparently indifferent to all qualifications), so that the lowest but one in the examination was voted for the berth? If the other candidates who showed better results in the test were unqualified in physique or other merits, could not their defects have been discovered earlier, and thus have spared them the gall of being passed over by inferior competitors, and, otherwise, where is the sense or humanity of these City Fathers stored to waste the time and brain power of the candidates? This instance, I think, is almost a fulfilment on earth of the scriptural saying that 'the last shall be first,' though perhaps not in the way intended when uttered." Our correspondent may not be able to discover the sense or humanity of the arrangements made by the Corporation, but he should remember that it is not sense or humanity which is paramount in Ireland, but fun; and if the Dublin Councillors have enjoyed themselves over the wasted labours of the candidates he ought to be pleased in having contributed his share of the amusement.

CATHEDRAL SERIES.—SALISBURY: EAST END OF CHOIR.

STAFFORD HOUSE, ST. JAMES'S.—GARDEN FRONT.

FOTA, NEAR CORK.—GARDEN HOUSE—ENTRANCE GATE.

THE Right Hon. A. H. SMITH-BARRY, M.P., has recently made considerable improvements in the gardens of Fota, near Queenstown, co. Cork. The gates standing in the middle of an old yew hedge, and the garden-house, which we illustrate this week, form part of the scheme. The grounds contain some remarkably fine specimens of foreign trees planted close on a century since. Many species rare in the United Kingdom are here flourishing in the greatest beauty. The architect is Mr. ARTHUR HILL, B.E., F.R.I.B.A.

## LIGHTHOUSES.

By ALFRED J. GLASSPOOL.

THE English race is pre-eminently the lover and master of the sea; upon this pre-eminence depends our life, nationally and physically. We are what we are, at home and abroad, because we are able to guard from foes the "silver streak" surrounding our little island. The Vikings' blood still flows in our veins, and although commercial greed has done much to make a sailor's life disliked, we still do and must continue to "rule the waves."

Pessimists who are continually croaking out their dirges on England's downfall have only to ascertain facts to discover that our commerce is yet the envy of the world. English ships are in every port, and ships of every nation turn their heads to our iron-bound coast. It is, then, our first duty to do all that is possible to protect our vessels and those of strangers who come to do trade in our harbours. We cannot command the storms either to arise or to cease; we may throw oil on the troubled waters, but they will still be agitated by the stormy winds; but we can place such signals in the track of the sailor as will help to keep him off hidden rocks and treacherous sands.

Perhaps one of the most interesting parts of English enterprise is to be found in these undertakings.

A delightful voyage on one of the excellent fleet of the British and Irish Steam Packet Company's from the London Docks to the port of Dublin has revealed to the writer the necessity of a variety of seamarks to protect vessels nearing our coast, and the study of these, as shown in the map forming the frontispiece of Mr. E. Price Edwards's instructive little book, "Our Seamarks," will show how well our coast is protected.

Even to indicate the numerous lights which attract our attention even on so short a journey would occupy far too much of our space. We have hardly got out of the river when we find ourselves looking at the Swim Middle light-vessel, having a white light and revolving at half-minute intervals; this is followed by the Maplin Sands light, red in colour, occulting with white sectors also at half-minute intervals; the North Foreland; the South Foreland, with its two electric white lights, the higher one visible twenty-six miles away, the lower at least twenty; then follows Dungeness, having two lights, high, white and fixed; we now become deeply interested in the light of St. Catherine's, Isle of Wight; then those of the Needles, where we see red and green sectors; then quickly in succession Portland Bill, Plymouth Breakwater, the Eddystone, the Lizard, the Wolf Rock, St. Agnes, Scilly, the Bishop Rock, Scilly, and the Longships Rock, Land's End.

Then making our way across St. George's Channel, we steam by the Irish Sea, and see on our right the Bardsey, the South Slack, the Holyhead Breakwater and the Skerries; on our left the Hook Tower, the Waterford, the Tuskar Rock, the Arklow, the Wicklow Head and the Howth Bailly; in all at least fifty lighthouses and lightships, all efficiently maintained at great cost to protect this portion of our coast.

To the landsman, pent up in a close office all the year round, and passing only to and from home to business, the wide open sea, the exhilarating breezes, the frowning coast line, the strong forms of the lighthouses, bidding defiance to the storm, and the tender, almost motherly, light flashing forth in the darkness, awaken thoughts and stir emotions quite impossible to express, and convince the beholder that it is more than ever true that those who do business on the waters behold great wonders.

But it was not always so. Just as the lighting of a great city has been the growth of years, just as now we can venture out at any time of the night and find every street and alley of a well-lighted city protected by its gas lamps or its electric light, whereas our forefathers had to carry torches or lamps to find their way amid darkness and filth and thieves, so the guiding lights of the sea have only been achieved after much labour, loss and disappointment.

The necessity for some indication to guide ships, both by day and night, was always evident to the most thoughtless observer; but now that geology has accomplished such great strides, and the bed of the sea is becoming known as thoroughly as the land routes of a great continent, the importance of indicating the sea lanes, the high roads and turning points of the sea becomes more and more evident.

Frost, heat, rains, floods, currents, all have a share in placing dangers in the way of the mariner. The suspended matter brought down by rivers—shingle, sand, mud—are deposited in various parts at the mouths of rivers; these are subjected to movement by the action of the waves. The waves beating upon the coast break off great masses of land; these are carried away and help to form barriers to the progress of our ships.

Volcanic action in remote ages has caused mountain ranges to sink so that their tops now at times just peep up above the waters, or are covered by the waves, and thus present a continual menace to those who are obliged to make their journey in their midst.

If civilisation and firm government have rid the sea of rovers

and pirates, there remain still more treacherous enemies waiting to embrace the sailor in their grasp.

As a protection against such deadly foes the lighthouse stands as a smiling friend—by day a landmark indicating to the sailor his position, by night sending forth its cheering beams guiding him on his way, as it warns him against sandbanks, shoals and rocks.

We know that the ancients had the germ of our present lighthouse system when they erected the Pharos at Alexandria, the Colossus at Rhodes, and the well-known Caesar's altar at Dover. The beacon fires, though imperfect and often delusive, yet indicated a desire to help those who hugged the shore and "feared to launch away."

Our sailors, up to the time of Henry VIII. and his illustrious daughter Queen Elizabeth, depended very much upon the natural formation of the coast, the steeples of churches, and other indications to guide them over the sea. When the commerce of England began to expand, larger ships being built and much trade being carried on especially between England and Antwerp, it became essential that some means should be adopted by which our ships should be protected.

It was in 1536 that a maritime society known as the Trinity House, Newcastle-upon-Tyne, obtained a charter from Henry VIII. They had the privilege to "build, make and frame of stone, lime and sand, two towers, one on the northern part of Shelys (Shields), at the entrance to that part of the said town, and the other upon a hill there fit and convenient for signals, &c.," to carry out this work they were to levy certain tolls on shipping.

In the records of the Corporation of London there are several references to the towers thus erected, and a correspondence is referred to which took place between the Lords of the Council and the Lord Mayor with regard to the raising of tolls at the Port of London to maintain such towers. Ships were not allowed to enter a port till the dues for the lights had been paid. In 1581 a Bill was brought into the House of Commons "for maintaining a light upon Winterton Steeple, Lincolnshire, for the more safety of such ships as pass by that coast."

It is an interesting fact that in 1585 Sir Thomas Graye, in his own name, and in the name of the masters of Her Majesty's navy, and also on behalf of the seamen of Norfolk, petitioned the Lords of the Council for the maintenance of a watch light on the steeple at Winterton, thus showing how the steeples of churches were utilised to indicate the coast line.

James I. granted a patent to Sir John Meldrum for erecting lighthouses on the coast, a charge upon coals and a penny a ton upon all shipping to supply the necessary funds. This roused the opposition of the Trinity House, who petitioned against it, March 22, 1621. The record tells us that a great debate took place in the House of Commons on the matter, the result being that the patents for Winterton and Dungeness were condemned, April 18, 1621. It is obvious that the lighthouses first erected were only for local use. They guided the fishing craft into harbours, but were of little or no use to ships passing along the highway of the sea at a distance.

It was early in the seventeenth century that several simple massive towers were built on prominent headlands; on them were kept burning great fires of coal and wood. Such fire-towers had been in use in the Mediterranean for many years at the entrance to ports and harbours; they were now intended to serve a wider purpose.

It can be easily conceived that such a method of illumination must necessarily be very inefficient, and could ill serve its purpose. The great blaze of one moment or the red glow was succeeded, when new fuel was applied, by great clouds of smoke, hiding for a time all appearance of the landmark. Being open to the atmosphere such a light was exposed to all kinds of weather; wind, rain and snow played great havoc, and it was only with great difficulty that the fire was not entirely extinguished.

Another great evil consisted in the fact that the greater part of the light was sent up into the sky instead of over the waters to the ship who needed its warning blaze. Improvements were seen when the fire was enclosed in a kind of grate, showing its red embers to the sea, its black back to the land, while a further development placed a flat plate of brass at the back to act as a reflector.

The chandelier came afterwards, being placed in an enclosed lantern. The visitor to Plymouth Hoe may see the very chandelier which was placed in Smeaton's masterpiece, the old Eddystone, in which burned twenty-two candles, "whereof five make two pounds."

The number of lighthouses in modern days has greatly increased, there being over 500 on the coast of the United Kingdom.

In constructing a lighthouse, consideration has to be given first to the dangers of the coast, and afterwards to the comfort of the men who will have to spend their time within its boundary; so that, in selecting a spot for a lighthouse, all other things being equal, that spot is chosen where cottages

can be erected in which the men, with their wives and families, can reside. Thus we sometimes see the lighthouse surrounded with a cluster of whitewashed cottages glistening in the sunlight and forming a very pretty foreground to the wild scenery behind; at times the lighthouse and its surroundings are placed in out-of-the-way situations—at Spurn Point, for example, on the north shore of the Humber, there are two lighthouses and a coastguard station, altogether making quite a little community, many miles from the nearest village. On the Scotch and Irish coasts the lighthouses are often placed in such inaccessible spots that the children are unable to attend school, nor is there any place of worship within reachable distance; others are placed in very pleasant spots, and, like the North and South Foreland, are near fashionable watering-places. They have constantly many visitors, who are received most cordially and who can but come away much instructed by the information given, and the spotless cleanliness of the whole structure.

*(To be concluded.)*

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last, the president, Professor Aitchison, A.R.A., in the chair.

The minutes of the last meeting were taken as read.

Mr. H. H. Statham read his paper on

### The New Government Office Scheme.

In that room, he said, they were bound to consider the treatment of Government offices from an architectural point of view, both in regard to the most effective treatment of the buildings themselves, as an important element in our national architecture, and to those questions of alignment of streets which came under the general head of what were called "public improvements." The subject was one of national importance. In order to appreciate the present position it would be well to look back a little. It was obviously important both for architectural effect and convenience of communication that Government offices should be concentrated, and should be rebuilt from time to time in accordance with a definite scheme to which each new building would be a contribution. Such a scheme, on the grandest scale, had been drawn out by Sir Charles Barry in 1857, not only for the concentration of the Government offices, but for the improved laying out of the whole Westminster and Whitehall district. The greater part of that scheme was now rendered impossible by what had been done in a piecemeal way since; it was melancholy now to look at that plan and think what splendid possibilities had been lost, but he wished to draw attention to it and to include it in the Institute Journal, partly because it was well at least to have before our eyes a great ideal and also because, as he would show, one or two points in it were still capable of realisation. In 1856 took place the great competition, open to the world, for a plan for the concentration of the Government offices and for special designs for War Office and Foreign Office buildings, as the result of which the War Office, though there was the most urgent need for it, was abandoned, and Sir Gilbert Scott received the commission for the Foreign Office. It had been attempted to show that the Foreign Office was a complete failure, and a proof of the mistake of erecting palatial Government offices designed by an outside architect; but this was exaggeration, the faults which it had could easily be avoided in a future case; it was at all events a dignified building, and its quadrangle of the dimensions of 240 feet by 170 feet was on such a scale as to have a really fine effect. The argument that such buildings would be better produced by the official surveyors of the Office of Works was sufficiently answered by the buildings which were so produced—notably the post offices, which were nearly all in a poor and commonplace style of architecture. In 1882 the competition for new War and Admiralty Offices was announced, not on the Great George Street site, as had been expected, but on a site near Spring Gardens, in which a part of the new building, for economy and to avoid purchasing some street property on the west side of Whitehall, was relegated to the rear of the houses. The opportunity afforded for widening the upper end of Whitehall by throwing back the west line of the street, pressed on the committee by two eminent architects, was entirely ignored. The next step was that this scheme was abandoned, the building of the War Office was again postponed, and the committee of 1887 reported that the Admiralty could be economically provided for by retaining and adding to the old Admiralty buildings. He could not understand how any Government could sanction the retaining of a building with such an interior as that of the old Admiralty; nothing short of entirely gutting it could enable it to be made a satisfactory building, and the architectural exterior was not worth that. The new buildings, though well planned, represented a design originally commonplace though rich and costly, cut down to a cheap brick structure with stone dressings; the superficial richness being removed, only the commonplace remained. As

a building for the administration of the greatest naval power in the world, it was little short of a disgrace to the nation. Coming to the Parliament Street site, the new proposed buildings there would be well situated parallel with the Foreign Office, but in order to produce their proper effect the design ought to range in its main lines with that of the Foreign Office and harmonise with it in character; to erect an inferior type of building would be to destroy the whole architectural effect. The alternative proposal to set back the Parliament Street part of the new buildings at an oblique angle, merely with the object of getting a full view of Westminster Abbey from a point 80 yards higher up Parliament Street, was absurd; it would be spoiling the whole building and throwing away part of a site, already too small, for an almost imaginary benefit. Coming to the question of the War Office, the fact that the money had been voted for the Carrington House site surely did not bind the Government either to build War Offices and no other on that site, or to decline enlarging the site by the purchase of further property. It would be quite possible still to build the War Offices on the Downing Street site, and to provide for the departments, now on that site, on the Carrington House site. This would realise, with some modification, Barry's fine conception of the War Office and the Admiralty Office as symmetrical blocks on either side of the parade ground, the Horse Guards in the centre. Probably none of the buildings on the Downing Street site could be permanently retained in such a case—the interior of the Treasury building even was too old-fashioned to retain; but the little domed vestibule of Dover House ought to be respected in any case, and could easily be worked into a new building. The vote for the Carrington House site had been unexpectedly taken; it was distinctly promised that the committee would hold further sittings first, and it might be observed that for the first time, he believed, no architectural evidence at all had been taken on a scheme so important in the architectural embellishment of the capital. The official plan for the building on this site was a double mistake. In the first place, the shape of the building was to be settled by the irregular shape of the intersecting streets. That was an estate agent's and not an architect's way of planning; it was reducing what ought to be a national architectural work to the level of a block of flats or a monster hotel. In the next place the site would be overbuilt both for architectural effect and sanitary conditions; the largest quadrangle into which rooms would look was only 105 by 100 feet for a building five storeys high. They might compare that in their minds with the quadrangle of the Foreign Office, the same height and 240 by 170 feet, or a model which he had there would show the facts still better. There was nothing to prevent acquiring some further property north of Whitehall Place, and treating that portion of the building in symmetrical architectural relation with the courtyard of the old Admiralty, if that really was to be retained. There was no objection to building up Whitehall Place; it was shown that it was now an unnecessary street as far as traffic connection was concerned. The rest of the building could be planned symmetrically on the greater portion of the Carrington House site, the building line on the south side being brought in a little so as to make Horse Guards Avenue central with the Horse Guards, as it always ought to have been. It was absurd that a street facing a famous building and named after it should have been laid down out of centre with it; such a plan would be laughed at in Paris, but in London the alignment of streets and buildings was utterly ignored. Having got the extra width, they might then also make Horse Guards Avenue a real "avenue" by planting two lines of trees in it. When on the subject of what might be done, it was fascinating to go a little further and sketch out a really stately scheme for the combined treatment of the Admiralty and War Office. Suppose the old Admiralty removed, the new block already built might be lengthened southward a little, and returned towards Whitehall, with a similar northern block built on the foundations now being laid. On the centre of the fourth side of the quadrangle thus formed, facing Whitehall, would be the First Lord's House, with a columned screen and entrance on each side of it. Opposite to this we would buy up all the east side of Whitehall up to Craig's Court, and plan the War Office with a similar but shallower courtyard facing the quadrangle of the Admiralty, and the Commander-in-Chief's house or staff offices in the centre, facing the First Lord's house. The new block of the Admiralty would be retained in its interior plan, but faced with stone to form part of a new and superior architectural design. The whole west side of Whitehall up to Charing Cross would be set back on a new line to give it an equal width all the way up, and, above all, to connect it with the axial line of Trafalgar Square, the Charles I. statue being moved a few feet to get it also on the point of meeting of the axis of Whitehall and the Square. The Mall would be continued through in a straight line into Charing Cross, the space between that and the Admiralty being occupied by street buildings forming the offices of the Woods and Forests and one or two other small departments. Speaking of that reminded

him that the official plan showed the Mall continued through in the same way, but evidence had been given before the recent committee by Police-Superintendent Beard that it would be bad for heavy traffic to come out of the Mall on to the slope of Charing Cross, that the exit ought to be taken up at an angle into Trafalgar Square. This, however, was beside the mark; if the Mall were to be given up to heavy traffic it had better remain closed, and the very object of opening it was the straight vista along it. He had spoken plainly on the matter of the buildings because it was a subject of national importance. Architecture was not everything, but in history it would be observed that the effort to produce great buildings was coincident with the greatness and ambition of a nation in other respects; it was when a people was going downhill that national architecture was neglected. This looked bad for us, when we got to the point that the attitude of our Government towards architecture reminded us of Mephistopheles' definition of himself, "I am that which says 'No' to everything." The Government had one chance yet left to do something fine with a War Office, something to atone for the long series of blunders with public buildings in this country, in regard to which one might say, "They have made us a by-word among the people, a very scorn and derision to them that are round about us."

Mr. H. W. Brewer, who was asked to commence the discussion, said the question was too big a thing for him to deal with, and he felt overwhelmed at the thought of it. Were we or were we not to have Government buildings? The general feeling of Englishmen was that we should not. The loss the nation had sustained some years back when documents which had to be referred to had been found missing or spoilt seemed to have brought our countrymen from the error of their ways. The records then were kept, in sixteen or eighteen different places, and to search for one meant great labour and more often fruitless toil. Probably nothing would have been done to provide a Record Office, but that at a committee inspection of records the documents were found to be nearly spoilt by damp or else eaten by rats. The destruction of the Admiralty would not cause much sorrow, as the old place was not interesting, but in the case of its coming down he hoped the board-room would be taken care of and preserved. The prolongation of the Mall was one of great importance, and it happened that Charing Cross had to be struck out of the Jubilee procession because there was no means of getting back to Buckingham Palace. The speaker proposed a vote of thanks to the reader of the paper.

Mr. W. Woodward, who seconded the vote, thought Mr. Statham had been too hard on the Office of Works, and had also been distinctly unfair. The plans were produced most rapidly, and in the evidence before the Select Committee Mr. Taylor said that they were to be taken only as sketch drawings and not as matured results. Not one single elevation had been prepared by the Office of Works. With regard to the architecture it was easy for any gentleman to make comparisons and disagree. In speaking of Government buildings, Mr. Statham, he said, had omitted one, and that was the Royal Courts of Justice. After it was designed the Office of Works had to put right what the architect had left undone, and therefore much of the criticism would necessarily fall to the ground. If a bridge was preferable to a subway, perhaps the lecturer had not considered the question of lifts. The speaker disagreed entirely with Mr. Statham's views, and it was beyond his comprehension how any man could advise the retention of such a place as Dover House.

Mr. E. W. Mountford said it had been proposed to have an evening with regard to the County Hall, which would have brought in the question of widening the Mall, of which Mr. Statham had said something. If the Mall was to be improved at all, it should be widened to its whole width, and turned north. Going south it would be necessary to remove Drummond's bank, which was not a beautiful specimen of architecture, and then make Nelson's Column and the National Gallery a centre. Scott's building was not according to his original design, which was Gothic, and there was much left undone in the existing building which, if carried out, would have made it assume a more satisfactory appearance. The Law Courts also did not deserve all the blame which was expressed about the building. Judges were hard to please, and the recollections of the old courts at Westminster Hall had not died out among them. One of the causes of the shortcomings arose from the inadequacy of the space to accommodate such a variety of courts and offices.

Mr. W. D. Caröe and Mr. E. W. Hudson continued the discussion.

Mr. John Burns said he did not intend to follow the reader in his details. The committee were not, however, such vandals as had been supposed. They had no intention of excluding the evidence of non-official architects, and it would be an advantage if two architects were deputed to explain the views of the Institute before the committee. For his own part, he must own he did not approve either of Mr. Statham's proposals or those of the Office of Works. His views would be found described in the Blue-book containing a report of the proceedings of the com-

mittee. More could be made out of the Carrington House site.

The President spoke of the different sort of arrangement which was adopted in Florence when the cathedral had to be covered. There the effort was to obtain the finest effect. Modern English architects were ignored by the authorities as well as by the people. They could not be compared with writers who enjoyed popularity. He did not care much for giving importance to the Nelson Column as a centre, for it helped to conceal the National Gallery.

Mr. Statham, in reply, said he was glad to learn from Mr. Burns that non-official architects would be heard by the committee. There was a relation between the spirit of a country and the character of its public buildings.

## THE NATIONAL GALLERY.

THE report for 1896 of the trustees and director of the National Gallery, Sir Edward Poynter, gives the usual list of the pictures bought and presented during the year, the loans to various institutions, and other particulars. The gallery was visited by 489,842 persons on public days during the year, a daily average of 2,343. The number of visitors was highest in August, when the attendance reached 65,828 for the eighteen public days of the month, and in April, when there were 65,542 visitors on the seventeen public days, the months of September, May, October, July, March, June, February, January and November coming next in order; while the gallery received the poorest patronage in December, when there were 23,985 visitors on the eighteen public days. In addition, 29,607 persons visited the gallery on the twenty Sunday afternoons on which it was open. On students' days (Thursdays and Fridays) 42,580 persons were admitted, the admission fees amounting to 1,064*l.* 10*s.*, as compared with 1,037*l.* 17*s.* 6*d.* in 1895. The total number of students' attendances on Thursdays and Fridays was 20,057, and 999 oil-colour copies of pictures were made, 601 being British and modern, and 398 foreign schools.

In the report there is no information about the pictures selected by the copyists. All that is stated is that 87 of the 151 pictures were by foreign masters and 64 by British masters. In all 13,029 copies of the catalogues were sold, nearly one-half the number representing the sixpenny catalogue of the British and modern schools. Only seventeen copies of the 3*s.* catalogue were sold during the year.

The following pictures were purchased:—"The Picnic" (La merienda campestre), "The Bewitched" (El hechizado por fuerza), and both by Francisco Goya, the price being 265*l.* 14*s.*; "Portrait of Doña Isabel Porcel," by Francisco Goya (404*l.* 19*s.* 10*d.*); "Jupiter and Semele," by Andrea Schiavone (42*l.*); "Symbolic representation of the Crucifixion," by Giovanni Mansueti (435*l.* 14*s.*); "A Winter Scene," by Hendrik van Avercamp (89*l.* 5*s.*); "Portrait of Himself," by Gilbert Stuart (105*l.*).

The bequests and donations were as follows:—"The Crucifixion," by Spinello Aretino; "A Calm at Sea," by Charles Brooking; "The Moorland," by John W. Inchbold; "Portrait of a Lady," ascribed to Antony Mor; "Three Sketches (in one frame) of Rustic Figures," by W. F. Witherington; five miniature portraits set in frames as locketts, viz. "Mrs. Burrell," of Beckenham, "A Lady," "A Young Girl," "A Lady," "A Military Officer"; a miniature, supposed to represent the Young Pretender, painter unknown; "Portrait of Mrs. Siddons," by Sir T. Lawrence, P.R.A.; "Portrait of Miss J. E. Gordon," by Sir David Wilkie, R.A.; six sketches (in one frame), by Sir David Wilkie, R.A.; "Interior of Beckenham Church," by David Cox; "Portrait of Lady Clarges," by J. Downman; "A Study of Still Life," by Willem K. Heda; "A Battle Scene," by Jacob Weier; "Dredging on the Medway," by William J. Müller; "The Philosopher," by Cornelius P. Bega; "Portrait of Miss Gainsborough," by Thomas Gainsborough, R.A.; "Two Dogs: Tristram and Fox," by the same; "Study of an Old Horse," by the same; "Landscape," by the same; "Landscape," by the same; "Rustics with Donkeys," by the same; "Portrait of Thomas Gainsborough, R.A.," by Johann Zoffany, R.A.; "Nature Blowing Bubbles for her Children," by William Hilton, R.A.; "The Last Day in the Old Home," by Robert B. Martineau.

Of the six collections of Turner's drawings and sketches available for temporary loan to provincial institutions, Nos. 1 and 2 still remain at the Grosvenor Museum, Chester, and the Blackburn Art Gallery respectively, No. 3 has been lent to the Ipswich Art Gallery, No. 4 to the Leeds Art Gallery, and Nos. 5 and 6 remain at present deposited in the National Gallery.

George Cruickshank's picture, entitled "The Worship of Bacchus," which has been lent since January 1894 to the Albert Institute, at Dundee, has been returned to the National Gallery.

In conformity with the provisions of the National Gallery Loan Act of 1883, the following pictures have been lent:—

"Venice, Noon, from the Canal of St. Mark," by J. M. W. Turner, R.A.; "Highland Cottage Interior," by Alexander Fraser; "Crossing the Ford," by William Mulready, R.A.; "The Deluge," by William Westall; "Æneas and the Sibyl—Lake Avernus," by J. M. W. Turner, R.A.; "The Battle of Trafalgar," by the same; "A Woodland Dance," by Thomas Stothard, R.A.; "The Battle of the Borodino," by George Jones, R.A.

The eight pictures belonging to the National Gallery which have been on loan in the Oldham Art Gallery since 1884 were returned in July last for repair; the surface of each picture having been cleaned and some of the frames repaired they were again lent to the Oldham Art Gallery in September. The National Gallery board assented to the exchange of the following pictures lent to the Stockport Museum in 1884—"The Gouty Angler," by Theodore Lane; "Buttermere Lake," by J. M. W. Turner, R.A.; "The Visit to the Tomb," by J. M. W. Turner, R.A.—for the following pictures lent by the National Gallery in 1895 to the Peel Park Museum at Salford:—"The Burning Fiery Furnace," by George Jones, R.A.; "A Basket of Fruit," by George Lance; "Dutch Shipping," by P. J. Clays.

### CANTERBURY CATHEDRAL.

ABOUT three-fourths of the sum mentioned by Dean Farrar in his Thirteenth Centenary Celebration Fund Appeal has now been subscribed, and excellent progress is being made with the work of restoration, which, it is hoped, will be almost complete in those portions of the cathedral at present under treatment by the time—next July—of the great gathering of Pan Anglican bishops in Canterbury. The careful system of treatment to which the crypt has been subjected has revealed frescoes and paintings on the vaulting which had been hidden for a very long time. Not only have the French texts inscribed by the Huguenots in the early days of their worship in the crypt been left untouched, but the text over the bay facing the Black Prince's Chantry (at present used by the descendants of the Huguenot refugees) remains as an evidence of their recent occupation of the south aisle. At places there were remains of as many as twenty coats of whitewash on the vaulting and stonework, but the whole of these have been removed. For centuries past the crypt has been open to wind and rain, but the whole of the window openings have now been glazed, gas illumination introduced, and a warm dry condition of things has succeeded the former damp, cold and dreary state. The lowering of the floor to its original level and the covering of the entire area with concrete has proved an immense improvement to this interesting substructure, bringing into view the bases of the columns and restoring the original beautiful proportions. In compliance with antiquarian desires, the brickwork filling the arches leading to the apse of the chapel of St. Gabriel is to remain for the present at least. It has probably been there since about the year 1400, and obstructs the view of some very fine and probably some of the earliest Norman frescoes in the world. A most interesting discovery, made in the course of the excavation of the floor of the crypt, is that of a stone coffin of the date of the twelfth century, almost precisely similar to that of Stephen Langton in the Warriors' Chapel.

The preservation of the cloisters has also been taken in hand. The zinc roofing was found, on examination, to be leaky everywhere; the supporting timbers, too, had mouldered into touchwood in many places, and the vaulting was defective. The timbers, &c., have now been made good, and an entirely new lead roof constructed. Work in the chapter-house is also well in hand. The structural safety of the roof and ceiling has been secured, and the latter is now being re-decorated in its original handsome design. The windows on the south side have been opened out and glazed, that at the west end reglazed and that at the east end is to be occupied by the stained-glass to be presented by the Freemasons of Kent. The masonry is also receiving careful attention, Purbeck marble (the stone originally used) being largely employed to replace that which is defective. The carved work at the east end is found to be in very fair condition, but there is considerable redecoration to be carried out. The bells of the cathedral are now to receive attention, and the Dean and Chapter are very anxious to accomplish the restoration of Bell Harry Tower. This is perfectly sound structurally, but the surface and the decorative tracery were some years ago reported upon as needing attention. This view is now emphasised by Sir Arthur Blomfield. The magnitude of this part of the restoration may be gathered from the fact that the erection of scaffolding would alone cost about 1,000*l.*, and it must depend largely upon the continued inflow of subscriptions to the Restoration Fund whether this work is possible. That it is necessary is shown by the occasional fall of pieces of masonry on to the roof of the cathedral, and by such inspection of the structure as is at present possible.

### THE PREVENTION OF FIRES DUE TO LEAKAGE OF ELECTRICITY.\*

#### Introduction.

IT is scarcely sixteen years ago since the attention of the fire-insurance offices was first directed to a class of hazards previously unknown to them, viz. the danger to property arising from the use of electric current for furnishing power and light. The currents which then came into use were proportionately immensely larger than those previously used for telegraphic and other purposes, and now represent possibilities of energy which can be measured only in hundreds of horse-power.

Many will still remember the "danger scare" created about the year 1880 or 1881 upon the introduction of electric lighting by reason of the crude methods of wiring which were first adopted. Science and art, however, are in their nature necessarily progressive, and necessity has encouraged improvement and invention. In respect of electric wiring the increase in the demand for electric light has provided wider experience and demonstrated new wants. Public confidence has gradually become re-established, and it is now felt that the elements of great hazard are not necessarily inherent in all electric work, and that fires are preventable within the limits of ordinary wiring practice.

As this improved state of affairs must be ascribed more or less to the initial action taken by the various insurance companies—who ostensibly, for their own protection, posed as authorities, took the reins of guidance and produced "Rules" for the purpose of ordering "safe wiring"—it may perhaps seem somewhat inconsistent to suggest that their rules may now even bar the way to further progress. Consideration of this paper may, however, show that in the light of increased experience and with the lapse of time conditions are arising which prevent the rigid and consistent enforcement of the rules, and so failing to provide perfect safety and reliability they are becoming antiquated and inoperative.

Although we are having fires caused by electric agency, of recent years we have escaped those of such a nature that public attention would be called to them, and confidence as to the relative safety of electric light has been secured. This acknowledgment becomes all the more desirable for us to retain when it has to be admitted that, even with our restored reputation, there still lurks ominously in the public mind an undefined presentiment that electricity and electric fittings of all kinds are in some way "dangerous"—if only as presenting to the lay mind the possibility of an accidental shock.

It must, however, always remain a matter of congratulation that the early action on the part of our fire offices has so far enabled the electrical industry in England to escape the effect and criticism which would arise from the frequent occurrence of insidious and destructive fires caused through defective electrical installation work.

The problem of safe wiring is therefore of the utmost importance and involves the main interest and welfare of the electrical industry. The writer will seek to prove that the greatest "safety" is to be found in adopting the best means of securing and maintaining "perfect insulation," so that it becomes necessary to enumerate the principles that we have to follow, and to ascertain the conditions under which they have to be applied.

Perhaps before proceeding in our review of the present methods of wiring it will be helpful to take a momentary retrospect of the development of an analogous service, viz. that of gas. When gas was first introduced, many crude methods of installation were adopted, such as glass tubes, tinned iron or copper pipes. These practices gave the needful experience which ultimately led up to the employment of iron pipes, the use of which, indeed, sprang from the utilisation of old worn-out gun barrels, until the increasing demand for gas stimulated the production of wrought-iron pipes.

King's treatise on the "History of Gas Lighting" states that gas-piping service was at first very costly and cumbersome, and remained so until Whitehouse, in the year 1825, took out patents for improvements in the manufacture of wrought-iron pipe and produced it by machinery. It was the lower first-cost of installation due to this improvement in production of gas-pipes which afforded means for the general advancement of gas lighting, as it is on record that the chief impetus in gas consumption dates from the year 1830, that is the time when Mr. (afterwards Sir) James Russell took over Whitehouse's works and patents and largely increased the production of low-cost iron gas piping.

#### Conditions.

In order to compare the practice of "gas piping" with "electric wiring" we have to bear in mind the anomaly that electricity needs, instead of an orifice, a solid material as its conducting channel. The metal copper, owing to its good

\* The Fothergill Prize Essay, by Mr. Frederick Bathurst, A.I.E.E., published in the Society of Arts Journal.

electrical conducting properties, has by universal consent become the favourite material to employ.

A length of copper wire affords a simple means of transferring electrical energy from point to point.

This energy, according to the transmitting or transmitting device employed, may be caused to show itself as light, power, heat or chemical action. A part of the energy thus transmitted disappears in the conducting wire itself, according to the opposition or "resistance" offered. This resistance varies directly as the length, inversely as the cross section of the conductor and according to the specific conducting capacity of the material used, each conducting material possessing its particular specific resistance. Metals have, as a rule, the least resistance and are therefore usually selected as conductors. The portion of energy dissipated in the conductor because of its resistance really reappears in the form of heat, which action increases the temperature of the conductor above its surroundings, and unless the size or "sectional area" of the conducting medium is properly proportioned to the energy to be carried, this heating action may, from a fire-risk point of view, become serious—an over-taxed wire readily becoming hot enough to set fire to any inflammable material in contact with it. The conventional safe working current for copper wires has been fixed at 1,000 amperes per square inch of cross sectional area. The energy it is possible to pass through a wire is dependent upon the pressure or "voltage" at which the electrical supply is effected, and is measured by the product of the pressure or "voltage" multiplied by the ampere flow of current. The pressure or "voltage" which represents such an important factor in electrical supply may by the non-technical be taken as representing the power of the current to force its way along the conducting path by overcoming the resistance. The "voltage" also determines the ability of the energy transmitted to break through any environment for "insulation" which has been provided for the purpose of confining the current entirely to its conducting path.

As in the case of fluids where suitable pipes must be made and joints provided with a due consideration of the pressure they have to sustain, so also in electrical service, the metallic conductor has to be regarded in respect to these conditions, for, as "pressure" can burst a pipe, so "voltage" can puncture or pierce insulation.

Silk, cotton, rubber and other insulating coverings have been placed upon wire for the purpose of confining the current to its proper path. These materials in comparison with a metal like copper are such poor conducting mediums in themselves that they may be termed non-conductors or "insulators." The function of all insulators is to surround the conducting path with a non-conducting wall so as to prevent any extraneous deviation or "leakage" of current between the point of generation or supply and that of utilisation.

We see then that in the analogy between gas-pipe service and electric-wire service it is the frail insulating covering of the electric wire which corresponds to the substantial metallic coat which forms the gas-pipe.

Since in every electrical path or circuit we have a pressure or voltage constantly striving to break through the insulating covering, it is evident that the problem of safe and effective wiring is to secure and maintain perfect insulation for the conductors throughout their length and treatment. It becomes necessary, therefore, to study the nature and conditions of the insulating materials available.

Speaking generally of insulating materials, it is found that the influence of "moisture" upon them is very deleterious, for moisture being itself a conductor causes any insulating material absorbing it to lose its insulating property. A current leaking through a moisture permeated insulating material produces heat, the material itself becomes charred, and entirely loses its insulating properties, all its specific virtue being ultimately destroyed.

As an insulating covering may be subjected to the influences of heat arising from the conductor itself carrying excessive current, it is obvious that we should use an insulating material which is little affected by heat, although we find that our choice has to be modified by the consideration that heat-resisting materials are usually very great moisture absorbents.

In practice, moreover, insulated wires may be subjected to rough usage; it is important, therefore, to find materials which have sufficient inherent strength to withstand the physical vicissitudes.

In buildings wiring is everywhere adjacent to wood or brick-work, or in contact with plaster and cement. These building materials, when dry, may be classed as insulators; but if damp they are, on the contrary, fair conductors, and able to act upon the insulating covering chemically, so as to eventually destroy its insulating properties. A current leakage into plaster or brickwork at some one point may not in itself cause serious damage, but the fact of its having "earthed" a portion of the circuit makes its hazardous for the same occurrence happening in another place. If leakage only presented a temporary interference to the working of an installation and the convenience of

the user, it still should be avoided; but experience also shows that when backed by a dynamo and steam-engine, sufficient heat energy can be developed to cause a fire. Time, heat, cold, chemical action and moisture are all powerful influences that may tend to deteriorate any of the insulating materials in use commercially; whilst, in addition, accidental damage of the material in the process of manufacture or installation must also be reckoned with.

Incipient electrical faults, such as above referred to, are not readily detected—usually only when a sensational notice of the defect is given. This possibility therefore further accentuates the necessity of insisting upon good work and the right conditions to start with.

An insulator to be perfect should be one that will keep its insulating properties under all conditions of temperature, being non-corrodible, durable, moisture-proof, fire-resisting and a reliable armouring. This combination of qualities is at present only partially provided in commercial work, and considering the growing tendency to increase the voltage of supply, this "insulation" problem represents a strife between the power of penetrating and the power of resisting with an all too favourable possibility on the side of penetration.

### *Experience.*

The first electric wiring was done with wires very inadequately insulated and these were usually fastened directly against the nearest convenient support, with iron staples, brass saddles, or later with wooden cleats. If the insulation was not mechanically damaged nor the wires overloaded, and everything was kept quite dry, trouble would not perhaps be immediately experienced, but the natural moisture of the atmosphere or accidental conditions soon caused imperfections.

The leaking current could set fire to the partially insulating materials by gradually consuming minute particles, until the semi-conducting gases so generated would combine into a destructive "arc," or if leakage occurs between wire and wire a "short circuit" would be created so as to cut the translating devices out of action and allow the whole current to pass through the defective point.

The heating effect of the current increases directly as the square of its ampere value, so that the amount of heat generated by the short-circuit rush of current at the defective point can become very great, sufficient indeed to melt the conductor itself and set the immediate surroundings on fire.

It is true that we seek to gain protection from such hazards by the use of "safety fuses"—thin strips of tin, or easily fusible lead-alloy wires—which melt and volatilise when an excessive current is passed through them and so automatically form a break in circuit, and a means of disrupting the current. Such fuses are arranged in non-combustible containing chambers, usually earthenware, which will not be damaged by the momentary heat generated by the arc when the fuse melts. A "fuse" is designed to give protection against overloading a circuit; it has, however, its limitations. An abnormal current takes time to heat the fusible metal to melting point, thus introducing an element of uncertainty. Furthermore, a fuse does not give protection against a leakage of current less than that required to fuse it. In other words, a fuse so small as five ampere capacity will not prevent a four ampere leak, whereas with favourable conditions a leakage current of two amperes can cause a fire.

Early wiring work was also defective in respect to design and workmanship, the electrical distribution being effected on what is known as the "tree" principle, in which a main wire feeds branch wires, and these again feed still smaller wires. Construction of this sort necessitates the use of a large number of fuse points and electrical joints, fuses being provided wherever it is necessary to make a junction of a small wire with a larger one. The joints presented many chances for imperfect work and unless carefully made would give trouble. If two wires are joined together the electrical resistance of contact depends upon the perfection of the union; a slight or partial contact, say on account of rough or dirty surfaces, may mean high resistance, resulting in the production of excessive heat. The insulation of the joint is also an operation which requires care and experience, in order that the new insulating covering should be perfectly waterproof and mechanical, and correspond in effectiveness to the original protection. Carelessness in handling wires, besides damaging the insulating covering may, in the case of a brittle conductor, result in partial fracture of the copper under the insulating coating. Under these conditions the wire may become heated and an arc occur at the ruptured ends which can set fire to the insulation. Wires, again, which are too small for the current they are to carry become over-heated, or the same result is attained if translating devices are changed or increased whilst the "fuse" has been purposely changed or strengthened to allow the increased current. Accidental contact of an imperfectly insulated wire carrying a relative high voltage, with another designed for low voltage, can result in damage to the latter. The improper placing of wires or lamps, or the defects arising from poor and

defective contact of binding posts and switch terminals, can all become fruitful sources of trouble and swell the number of conditions by which electrically caused fires may result.

Most insurance companies preface their rules for electric wiring by reciting the principal sources of danger to be anticipated, including them under the following headings:—

1. Inferior material and workmanship, particularly in joints, fittings and connections.
2. Conductors of inadequate size and conductivity.
3. Perishable and inferior insulating materials.
4. Dust, dirt and moisture.
5. Undue heating.
6. Neglect of frequent testing and inspection.

In the light of our previous examination of the possibilities by which electrical fires may ensue, we see that these conditions might be broadly summarised as troubles arising mainly under three headings:—

1. Imperfect insulation.
2. Imperfect conductivity.
3. Imperfect workmanship.

#### Results.

The insurance companies after their recitation of the danger conditions add a paragraph by way of confirmation that no installation will be accepted by them as a "risk" in which all these conditions are not adequately provided against. It has already been stated that hitherto the experience of the English fire insurance offices has apparently been a singularly fortunate one, and although each office may hold records of the actual electrical fires which have come under its notice, no attempt (so far as the author is aware) has been made to classify in detail the causes which have produced them. Some inspectors may even urge that the fires have been too few to give real indication as to weak points in English wiring practice, but whatever the argument advanced, the utility of examining and considering the experience of some other country can hardly be questioned. The author holds therefore that the remarkably rapid and extensive development of the electrical industry in America, even though attended with a great number of electrically caused fires, may, if we are willing to make an unprejudiced examination, put us in possession of much practical and useful data which can well be studied with profit to ourselves.

In the United States the insurance authorities have been forced by their serious losses to establish a special bureau whose sole work is to examine and test electrical apparatus, collect and record particulars of electrical fires, and determine in detail their probable origin and cause. The results and deductions are very carefully arranged and tabulated in quasi-public reports.

An examination of the reports\* of these electrically caused fires shows that a classification can be made under the headings we have already employed. We find that troubles from defective "insulation" or defective "conductivity" are included under the general term "conductors," whilst "inferior workmanship" includes constructive defects which occur in wiring material other than the conducting wires, as well as those arising from chance or accidental injuries. The records show that defects in "conductors" cause nearly 70 per cent. of the total fires occurring, whilst "imperfect workmanship" accounts for the remaining 30 per cent.

If we arrange the headings in a tabular form, we find that the defects of conductors are ascribed to "crosses," "grounds" (earth leakage) and "short circuits."

In fairness to our comparison, however, we should note that fully one-third of the "conductor" troubles arise from "crosses" between the wires of different systems of electrical supply, such as telephone and telegraphic wires, with electric light or electric railway "trolley" wires, and between the two latter systems themselves. These fires have been caused by insulation breaking down before a very much higher voltage than that it was intended to withstand, and would not have occurred if greater precaution had been taken to prevent such possibilities. They occur in the United States on account of the method of overhead wiring so largely followed for outside work upon the score of economy. They inculcate a lesson which may be taken as showing the wisdom from a fire-risk point of view of the English practice of putting all outdoor electric light or railway wires underground.

Analysing further, headings can be made showing that the "grounds" come chiefly from "structural ironwork," "moisture," "metal pipes," "nails" and "overloaded wires," whilst "short circuits" result from "unprotected wires through floors," "flexible cords," "metal pipes," "fixtures" (chandeliers and electroliers) and "wood casing."

Upon analysing the cases of fire which occur from "poor

workmanship" and "defective material," we see that "imperfect contacts" and "connections" alone give rise to as many fires as all those occurring in the translating devices themselves combined.

Tables I. and II. give in synthetic form the analysis of the conditions causing electric fires. The subdivisions may be taken as representing approximately equal numbers of fires, the most prolific cause in each section being placed first, the others ranging in relative order:—

TABLE I.  
DEFECTIVE "CONDUCTORS" CAUSE 70 PER CENT. OF THE ELECTRICAL FIRES RECORDED, AS THE RESULT OF—

"CROSSES" OCCURRING WITH	"GROUNDS" CAUSED THROUGH	"SHORT CIRCUITS" ARISING FROM
Telegraph or telephone wires with electric light wires. Do. with "trolley" wires. Electric light wires with "trolley" wires	Structural or other metallic work. Moisture (electrolytic trouble). Metal pipes (unprotected). Nails. Overloaded wires.	Unprotected wires through floors. Flexible cords. Metal pipes and fixtures. Wood casing.

TABLE II.  
"IMPERFECT WORKMANSHIP" AND DEFECTIVE MATERIALS CAUSE 30 PER CENT. OF THE ELECTRICAL FIRES, AND ARE—

"CARELESS" OR "ACCIDENTAL," RECORDED UNDER	(or) "INHERENT" OR "INCIPIENT," BY REASON OF
Imperfect contacts and connections.	Transformers. Safety fuses. Switches. Arc lamps. Incandescent lamps. Motors. Lightning discharges.

#### Deductions.

These records when examined give us not only a statement of the actual hazardous arrangement which was the cause of trouble, but point out also how the destructive effects could best be counteracted. They indicate firstly that "leakage" should be prevented as much as possible, and secondly that the formation of any arc consequent upon "leakage" or "short circuit" should, if possible, be localised in its effect. Further, it shows the necessity of somehow preserving intact the insulation of the wire, even though the troubles incidental to a conductor may arise. Although theoretically we endeavour to provide an insulating covering which may be considered sufficient to withstand ordinary usage, the occurrence of fire from such causes as "structural metal-work," "moisture," "metal pipes," "nails," &c., show the severity of the accidental conditions which may be encountered in practice. Wires are called upon to withstand damage from being dragged over rough floors, trodden upon by wiremen or labourers and other untoward damage incidental to construction work. We know that the waterproofing and moisture-resisting qualities of the insulated wires in use depend entirely upon the completeness of the covering, and also that the best material can be damaged by careless workmanship or unskilful manipulation; whilst it needs only the presence of moisture to set damaged insulating material on fire. We seek in practice to supplement this evident lack of essential mechanical qualities by providing that wires shall be installed in wood casing or metal pipes. But before examining the relative merit of these practices, should we not ask ourselves whether there is any possibility of gaining greater certainty from the insulating covering itself by making some other disposition of it which may be better suited to the conditions arising within or without it? Paradoxical as it may appear at first sight, insulating material, inflammable, if simply laid upon a wire, can in a large measure be made self-protecting if applied about a wire. Perhaps I can best illustrate the principle I wish to impress by taking an ordinary piece of paper, which is in itself inflammable and easily ignited from the flame of a lighted match. If the paper is now wrapped around itself so as to form a tube, although it can be ignited by an outside application of the flame it cannot be ignited by inserting the lighted match inside it. Practically it is impossible to maintain a flame within the limits of a tube scarcely larger in diameter than the burning material itself. Such an enclosure acts as a snuffer, and its quality of suffocating combustion is in a great measure independent of the inflammability of the material of which the snuffer may be composed. May not this principle be applied to the insulation of electric wires in order to meet the condition that the over-heating of an electric conductor can set fire to the insulation around it? Having noted this fact, we reach the point of this paper to demonstrate the advantages of a method of wiring, which is in reality a well-

\* The author would here acknowledge his indebtedness to Mr. William H. Merrill, jun., the electrician to the Electrical Bureau making these reports to the National Board of Fire Underwriters, for copies of same and permission to make extracts.

worked out scheme of supplementing (perhaps eventually even supplanting) the present method of attaching the insulation to the wire itself, by providing a system of insulating tubes into which the conducting wires can be drawn. Incidentally also, it may be shown that such a system of insulating tubes is not, as some have asserted, simply an additional charge on the first cost of an installation, but one which from its sufficiency, "reliability" and immunity from break-down brings more than sufficient economical compensation to merit any additional cost.

#### *Methods of Wiring.*

As before stated, the inherent lack of mechanical strength in insulating coverings is recognised and some method of protecting them adopted. In England most of the electric-wiring work has been installed in wood casing. Owing to the fact that the greater percentage of the work already done has been installed in old buildings which may be considered "dry," perhaps the slight property of mechanical protection that wood casing can give to an insulated conductor may, in this class of work, be considered as being fairly well utilised. Wood casing, however, possesses many defects; it can absorb and retain moisture, and retaining it will rot. If leakage occurs, the wood being inflammable will first char and then take fire. Being combustible it also presents a medium for spreading and increasing a fire.\* If desirous of proving the unsuitability of wood casing, the experiment should be performed of securing two conductors of opposite polarity on a wet board, when if the insulation on the wires has been damaged it will be found that "leakage" readily takes place, and that so small a current as 2 amperes is more than sufficient to set the wood on fire. Tests made by the United States Electrical Bureau show that wood casing can absorb moisture to the extent of 15 per cent. of its weight, and that every kind of treatment in the way of "painting" or "impregnating" with moisture-repelling varnishes or fire-resisting compounds must be considered ineffective, both from the electrical standpoint of "moisture-proofing" and from the fire-insurance standpoint of "fireproofing." The report on this matter expresses the opinion that wood is undesirable for "supporting or encasing electric conductors," and concludes with the significant remark that "it was to be hoped that fewer feet would be installed in future construction work." The main arguments advanced by advocates of wood casing are its ready applicability and its possibilities for decorative effects. Whilst these may, perhaps, have some merit if the location is dry and mechanical disturbance is unlikely, it will now probably be generally allowed that, in view of the uncertainty of maintaining the necessary conditions, wood-casing construction is certainly not applicable for new building work, and is certainly destined in time to be succeeded by more perfect methods.

Without wishing to make an evil prediction, the author would desire those insurance companies still upholding the use of wood casing to be on their guard lest they shall find themselves nurturing this practice under the aegis of tradition.

The demand for perfection in mechanical armouring has led to the introduction of ordinary iron pipes, and a considerable amount of wiring work is now going on in which the two electric wires are simply drawn into an iron pipe. The writer contends, however, that this is only an intermediate stage in the development of electric wiring, and that time will again demonstrate that the pipe protection must not only provide mechanical, but electrical, qualities also. In the case of plain unprotected metal piping, we know that the effect of imperfect insulation on one conductor at a single point may be transmitted throughout the piping system, and await the occurrence of a second fault at any point upon the other conductor. When this occurs, unless the fuses happen to be small enough in size and act properly, it is quite possible that a hole can be "burnt out" of the pipe at one or even both of the defective points. Those who urge that "fusing" can give protection in the above condition surely ascribe greater perfection to this device than is consistent with absolute safety. Most of the fuses in practical use will easily carry from 100 to 200 per cent. more current than their standard rating. Generally also the placement of the fuse is left to the judgment or experience of the constructing wireman and afterwards to whoever may be in charge of the installation, and should it at any time become necessary to increase or enlarge the translating devices, there is no means of counteracting the desire to replace a small fuse by one of greater carrying capacity. In any case, when it is shown that over-heating or leakage trouble can be obviated in a more perfect manner, I maintain that it is not the best practice to depend upon fuses as "safety" devices. Such fuse construction is certainly hazardous and seriously menaces perfect and uninterrupted service.

Again, those who state that they are willing to depend entirely upon the perfection of the insulating covering surround-

ing the conductors cannot surely have had practical experience with ordinary iron pipe construction. Anyone who has cut an iron pipe in two will allow that a "burr" is formed on the inside edges of the severed ends, which is sharp enough to abrade or tear any insulating covering. This means that every piece of plain iron pipe cut up on an electric wiring job must, if safety is to be ensured, be carefully and effectively reamed out. It is not satisfactory to feel dependent for good service and safety upon this condition, for can we hope that every wireman will give exact and careful attention to this point—or feel at ease in the hands of new or careless men? On the other hand, if an insulating lining is placed inside an iron pipe it inherently provides against the most wilful carelessness that can be suggested or the worst "burr" that can be made.

With an insulating lining all doubt is removed as to the interior smoothness of the tube, and, providing the proper thickness of lining is chosen, no burr can be caused to cut through it into the inside of the tube. The possibility of moisture and electrolytic trouble is prevented, and not only is the insulating material on the conductors placed under favourable preservative conditions, but the further safeguard is provided of an imperishable insulating protector permanently ensconced behind an effective iron armouring.

Furthermore, experience has demonstrated the necessity of insulating electric fixtures from the gas-piping of the building, because if this is not done a defect occurring on the electric fixture would be transmitted throughout the gas service. The insurance rules state that it is "entirely inadvisable" to combine electric-light fittings with gas-fittings, and allow such practice only under the protection of an insulating joint. Surely those who would advocate plain iron pipe for electric wiring, entirely overlook these determinations?

Many instances can already be quoted where the union of gas with electric fittings has resulted in disaster to both, either lighting agency having the ability to release the other. The author believes that practical experience will show that where gas or water systems are used concurrently in the same building with electric wires, unless an auxiliary insulation is provided between the insulated conductor and the metal piping system, unlooked for troubles will occur.

The main argument that can be advanced by plain iron pipe advocates—that of lower first cost—does not hold if regard is given to uninterrupted service and to the future.

At the present time there are advocates to be found for "earthed" wiring systems, one method suggested being the use of a single insulated wire within an ordinary iron pipe. The pipe is to form the return conductor, and is to be guarded against as such. Under the conditions which pertain to such a system the advantages arising from an insulated lining inside the pipe are apparent, because any over-heating of the conductor would be effectually guarded against, and there would not be the possibility of a "short circuit" burning out the iron pipe. It is also suggestive to notice that on such a metal-pipe-return concentric system an insulating joint at the fixture outlets would be entirely out of place, since its insertion would break the metallic continuity of the return circuit. Combination gasfittings connected with it would, therefore, present a fire hazard. On the other hand, a bare copper wire insulating-lining-metal-pipe concentric system would have the advantage in these respects. Although an "earthed" wiring system can be advocated on the score of low first cost, the writer believes that the difficulties it introduces (if not insurmountable in extended practice) should only be approached with diffidence, and therefore prefers (for the present) to advocate a system in which both lead and return conductors are insulated and enclosed under the covering of an armoured insulating tube.

(To be concluded.)

#### ABERDEEN UNIVERSITY BUILDINGS.

THE two ancient Universities of Aberdeen were amalgamated under the Act of 1858 as the University of Aberdeen, and the continuance in perpetuity of the University is provided for by the Act of Union between Scotland and England. In 1889 an Act was passed which devolved the buildings and property upon the University Court, and an annual grant was given by the Government, which, when reinforced by a share of the equivalent grant, amounts to 14,400*l.*, which has to be devoted to salaries, library and administration, except to the extent of about 700*l.*, which is available for repairs and maintenance of existing buildings, but not for the erection of new. The Act also provided for the appointment of a commission for organising and extending the scope and teaching power of the departments of the Scotch Universities, and the effect of the commissioners' ordinances on this University was to add a new faculty—that of science—as well as to expand the four former faculties, and largely to increase the building requirements in respect of laboratories, museums, &c., in almost all the departments of the University, while it made no provision for supplying the buildings to accommodate them. The University was

\* A conspicuous instance of this imperfection occurred so recently as October last at the Prince of Wales's Theatre, where a serious calamity was only averted by the effective action of those in charge.

in these circumstances, compelled to build, but had no funds for the purpose.

A movement was therefore started in 1891 for meeting this demand. A large and influential committee was formed, and application made to the Treasury for assistance. In 1892 Mr. Goschen, then Chancellor of the Exchequer, agreed to give a grant of 40,000*l.* if the public subscribed a similar sum. Up to the present the appeal has been successful with the public to the extent of 75,000*l.*, and, with the Government grant, 115,000*l.* have been raised and expended, while the works at present in progress entail a further liability upon the University of fully 21,000*l.* To meet this exigency, as well as to complete the buildings extension scheme and the still urgent necessities of the University, a total sum of at least 40,000*l.* is required.

In this jubilee year of the Queen's accession it is felt to be appropriate to make an appeal for the completion of a building whose foundation as a modern structure was laid in 1837, and which is therefore a coeval monument of Her Majesty's long and beneficent reign.

### GLASGOW ARCHITECTURAL ASSOCIATION.

AT a meeting of this Association, held in the rooms, 107 Pitt Street, on Tuesday, the 6th inst., Mr. Wm. Tait Conner, in the chair, Mr. Wm. Fraser read a paper on "The Influence of Economics on Architecture." He showed the bad effect the present land tenure had on architecture, how, especially where leases of a limited period existed, the buildings were built only to last out the lease; how building for profit, and not for use, tends to depreciate our art, as the great proportion of the buildings in Glasgow are erected by the speculative builder, whose aim is to make a profit, and not to erect the best building he can. He showed also how the unequal distribution of wealth, competition and the subdivision of labour were against the appreciation of good architecture and unfavourable to thoughtful design and good workmanship. The remedy he suggested was collectivism, which, he said, would give greater opportunities for good architecture, as buildings would only be erected when required, and not as profitable speculations. There would be no glaring inequalities in wealth with the ostentation of riches and the degradation of poverty. The worker would be well fed, and be sure of employment, and could therefore take greater delight in it and produce better things. There would be no need for work being cut down to the cheapest point to make things pay, for buildings would be erected for the good of the community, who would take a delight in seeing their own property beautiful. On the motion of Mr. James Craigie, a hearty vote of thanks was awarded to the essayist.

### OPEN SPACES IN LONDON.

THE joint committee of the Commons Preservation Society, the Kyrle Society, the Metropolitan Public Gardens Association and the National Trust for Places of Historic Interest or Natural Beauty have appealed for funds in order to acquire and preserve open spaces for the benefit of the Metropolis. The following are the spaces which it is considered desirable to secure:—

1. Riverside Ground, Wandsworth.—Twenty acres, in poor locality, price 31,300*l.* The District Board has agreed to give 10,000*l.*, and an application for a grant has been made to the London County Council, but it is expected that not less than 7,000*l.* will have to be raised from voluntary sources. Chelsea, Battersea, Putney and Fulham all possess public riverside grounds, Wandsworth only has none. A space adjacent to the Thames is equivalent to a far larger area inland.

2. Churchyard Bottom Wood, Highgate.—Fifty-three acres of charming woodland. The price, 25,000*l.*, named by the owners, the Ecclesiastical Commissioners, is extremely low. The offer holds good until June. Ten thousand pounds subscribed by the Hornsey District Council, 2,000*l.* by Islington Vestry, 3,000*l.* by residents in the locality, thus leaving about 10,000*l.* to be raised by a more extended appeal.

3. Bowes' Mahor, Wood Green.—Thirty-two acres of well-timbered estate, with an interesting old house, price about 20,000*l.* In a very rapidly increasing neighbourhood, the population chiefly consisting of the poorer and middle classes. If this opportunity is lost, no other land is available; earnest efforts are being made, and a local committee has been formed to promote the scheme, but outside help to the extent of about 10,000*l.* will probably be required.

4. Pymmes Park, Edmonton.—Fifty acres of park land, with an interesting house, price about 30,000*l.*; 30 acres of the above are already held on short lease as a public recreation ground by the district council. The council are anxious to buy the whole, which otherwise will be built on, but the district is too poor to purchase it unaided. The council would probably subscribe 10,000*l.* and have appealed to the committee for further help. Owing to workmen's trains with a

return fare of 2*d.*, there is a large and increasing influx of London working classes, the bigger houses being pulled down and replaced by cottages let at weekly rentals of 5*s.* to 10*s.* Population increased fourfold since 1871. Therefore this recreation ground is urgently required and should be saved from builders. About 15,000*l.* will be needed from outside.

5. The Chestnuts Estate, South Tottenham.—Eleven acres with good trees and house, price about 9,000*l.* The district council would probably purchase, if aided by voluntary assistance to the extent of about 4,000*l.* District similar in character to No. 4, only much larger and probably poorer, having a population of about 80,000, chiefly of the working classes. About four acres of common adjoin this estate, to which it would form an excellent addition.

It will be seen that some 50,000*l.* is requisite to supplement local efforts in order to carry out these five schemes for adding some 160 acres to the open spaces of London and its suburbs. Any persons whose interests may be aroused are earnestly invited to view the places or to make inquiries for themselves.

Funds will be received by this committee for any specific object or for application generally at the discretion of the committee, if the donor so prefer.

### EDINBURGH ARCHITECTURAL ASSOCIATION.

UNDER the leadership of Mr. Hippolyte Blanc, R.S.A., the members of this Association on the 10th inst. visited Niddry and Duntarvie Castles. The former, situated in Kirkliston parish, Mr. Blanc described as a fair example of an early keep, one showing the first development from the simple square tower. The doorway in the inner angle enters upon a circular staircase leading to the several floors, now in ruin. The walls average 9 feet thick. The foundation of the tower was ascribed to George, fourth Lord Seton, probably in the last quarter of the fifteenth century. The castle receives prominence in history as having in 1568 afforded shelter and protection to Queen Mary. During the troublous times of Charles I. and II. the castle and lands passed to the family of Hopetoun, the castle giving the title of Baron Niddry to Lord Hopetoun. Duntarvie Castle, situated in Abercorn parish, Mr. Blanc explained, was a residential manor-house of about 100 years later date than Niddry. It presents a large rectangular building, 80 feet long, facing south, with projecting wings at the extremes on the north side. This castle was in marked contrast to Niddry, the walls being so much thinner. There was much evidence to associate the period of foundation with the end of the sixteenth or beginning of the seventeenth century. The castle continued habitable until quite recently, and is now in ruin. Mr. Blanc was heartily thanked for his contributions.

### GENERAL.

The Rev. S. A. Barnett, whose Easter exhibitions of pictures during the last twenty-four years have been an advantage to Whitechapel, has appealed for funds to erect a permanent gallery in the parish. The cost of land, building and endowment would be at least 20,000*l.* Gifts amounting to 7,000*l.* have been offered, and a site adjoining the library, approved as sufficient by Mr. Harrison Townsend, architect of the Bishopsgate Institute, might be obtained if purchased within a fortnight.

The Corner-Stone of the new chancel of Croyland Abbey was laid on the 8th inst. The work now in progress is carried on as nearly as possible on the lines of the old work. The new chancel is simply the removal of the recently erected east end to the next bay or to the original western arch of the north transept. By this addition the unique Norman arch of the nave will be greatly strengthened.

The Sudden Death of Mr. R. S. Parker, the esteemed principal of the well-known building firm Patman & Fotheringham, of Theobald's Road, is announced. We are informed that the important business of the firm will in future be conducted by Messrs. James F. & Alfred E. Parker.

At the Ordinary General Meeting of the Surveyors' Institution held on the 5th inst., the president, Mr. Daniel Watney, in the chair, a paper was read by Mr. Walter Simms (Fellow), entitled "London—An Appreciation." The next ordinary general meeting will be held on Monday, April 26, when a paper will be read by Mr. W. H. Payne, L.C.C., entitled "Local Authorities and the Building Laws."

A Street in Volo, Thessaly, has been named after the late Mr. C. Chaloner Ogle, a young architect of great promise, who while on his travels in Greece had drifted into journalism, and was barbarously murdered in 1878 by the irregular soldiery under Amoussa Aga, a Turkish major and chief of the police in Thessaly, whose enmity he had incurred by his denunciation of an atrocious massacre at Boulgarini, a village near Volo.

# The Architect.

## THE WEEK.

AMONG Metropolitan builders until a comparatively recent time one of the most important firms was that of Messrs. LAWRENCE in Commercial Road, Lambeth. It was closely associated with City works, for the founder of the firm was WILLIAM LAWRENCE, of whom it is recorded, "that when the approaches to the new London Bridge furnished an opportunity, at that time unprecedented, for at once making large provisions for the necessities of a rapidly-increasing commerce and adorning a City which greatly needed the graceful art of the architect, Mr. LAWRENCE had sagacity enough to avail himself of the occasion and public spirit enough to improve it so as at once to decorate the Metropolis with creditable buildings and to lay the foundations of his own fortune." Four of his sons carried on the business of contracting during several years, and when they retired it was made over to their principal assistants, an example of generosity which is almost without parallel in the history of industrialism. One of the sons was the late Sir WILLIAM LAWRENCE, who died on Easter Sunday. He was one of the most respected notabilities in the City. Born in 1818, he succeeded his father as alderman of the Bread Street Ward in 1855. Three years afterwards he served as sheriff, and in 1864 he attained the dignity of Lord Mayor. During his mayoralty he opened Southwark Bridge after it was freed from toll. In 1865 Alderman WILLIAM LAWRENCE was elected as one of the members for the City. He was knighted in 1887. Sir WILLIAM LAWRENCE was one of the most useful members of the Corporation, and he used his position, as well as his wealth, in aid of many philanthropic works. His brother, Sir JAMES CLARKE LAWRENCE, is also an alderman, and a second brother is member of Parliament for the Truro division of Cornwall.

ON Easter Sunday the last service was held in the church of St. Pierre, Montmartre. The building is, in part, ancient, and is supposed to be in a dangerous condition. Accordingly the Government has ordered its demolition. A great many antiquaries are opposed to the decree. As the most ancient among the Paris churches it should, they say, be treated with more respect, and it can be made safe without an excessive outlay of money. Just now, however, officials are not disposed to rely on the judgment of architects. The collapse of the vaulting of the church at Brousse, in the diocese of Albi, when several of the congregation were killed, has had the usual effect of magnifying the indifference or the ignorance of architects, although ten years ago a local architect endeavoured to persuade the Administration about the danger of the building. That catastrophe was preceded by some others in Paris, and as a result of the prejudice there is not likely to be any reprieve of the church of St. Pierre. A part of the building dates from the twelfth century, but it is mainly of a much later period, and presents a combination of Renaissance and Gothic details. One municipal councillor is anxious to have the building upheld in order to convert it into a museum of the relics of Old Montmartre which are at present huddled in the Mairie.

THE sub-committee appointed by the Edinburgh Town Council to examine the sites suggested for the proposed Usher Hall have prepared their report. The adoption of the Charlotte Square site is recommended by a majority, although the opinion of those who are competent to judge in Edinburgh is opposed to it. The sub-committee say that if the Usher Hall is not erected on one side of the square the permanence of the square in its present form is not secured. The report offers the following explanation:—"Causes are at work which may render change inevitable; and, even if the Corporation in self-denial refrain from erecting the hall there because of a feeling that the design should not be interfered with or destroyed, the permanence of the design would not be secured, but would still be in constant danger. After buildings have stood for a hundred

years, while the developments and changes of the city around have been going on, and are still going on with ever-accelerating speed, it cannot be expected that these alone will be untouched by change. The causes which have changed Princes Street and St. Andrew Square from dwelling-houses to business premises of a money value which would have seemed fabulous to the citizens in the beginning of the century cannot be expected to spare Charlotte Square. Even if it be held that the present buildings in the square form an architectural feature of great value which cannot be found in any other part of the city and will never be reproduced, this does not form a reason for objecting to the hall being placed there, unless it is affirmed that in the public interest it is necessary to maintain this unique and characteristic feature permanently in its present form. But no proposal has been made to secure such permanence. If it is realised that change ere long is inevitable, would it not be better that the Corporation should have the control of the design which is to replace the present, rather than that it should be replaced by eleven different buildings of miscellaneous designs, and at different times, according to the tastes or requirements, for business or otherwise of the individual owners? The objection which rests on the idea of securing the continuance of the present symmetrical design loses much of its force when it is seen that the rejection of the proposal to place the hall there would not secure that continuance. In the case of CROALL against the Magistrates of Edinburgh, December 20, 1870, 9 Macpherson, 323, the Court of Session held that there is no binding restriction against the proprietors in Charlotte Square making alterations upon the elevations of their buildings, so long as they do not build upon their back greens. It would be too sanguine to expect that a site will remain for ever devoted to dwelling-houses which is required in the market for banks, insurance offices, and other business premises commanding a much higher price. It seems more probable that the process which has been seen in St. Andrew Square and Princes Street will be repeated in Charlotte Square ere many years are over, even if there was no proposal to place the new hall there. In fact, that proposal gives the only chance to secure the maintenance, in part at least, of the present façade and that any change shall be for a public purpose, instead of at the will of unconnected private owners." In conclusion the sub-committee recommend that the requisite steps should be taken for acquiring the site. It will be observed that the committee are not able to refer to any definite project for the transformation of the square with the exception of their own.

THE annual spring visits in connection with the Architectural and Building Construction classes of the Glasgow Technical College were made a few days ago—the places selected for special study this year being Edinburgh and Chester. The visit to the former city took place on Monday, 19th inst., when a party of about thirty students was conducted by Professor GOURLAY, who had made arrangements for studying the more important works of architectural interest—ancient and modern—in Edinburgh, including St. Giles's Cathedral, St. Mary's Cathedral, St. Margaret's Chapel in the Castle and the McEwan Hall, while the Museum of Science and Art received much attention in respect to its interesting collection of architectural and other remains. The visit to Chester was made by a party of ten students under the guidance of Mr. JAMES LOCKHEAD, A.R.I.B.A., and extended over four days, which time was principally occupied in studying by sketching, measuring and photographing in and about the cathedral, St. John's Church and the numerous half-timber houses and fronts with which the city abounds, and of which the time at disposal only permitted too brief an examination.

THE space which will be allowed to foreign exhibitors in the Paris International Exhibition of 1900 is to have an area of about twenty French hectares, or nearly fifty English acres. But the foreign demands, if satisfied, would need double that quantity. It has required a long series of calculations to arrive at the result, but the more delicate subject of allotting the space has next to be encountered by the authorities.

## JAMES GANDON.

THE names of English architects are so quickly forgotten, it behoves all who are able to use an opportunity to recall their services, if it were only momentarily, and especially to the minds of those who are destined to share a similar fate. Such an opportunity is now presented to describe the career of JAMES GANDON. His name was not thought worthy of mention in the "History of Modern Architecture" by the late Mr. FERGUSSON. But any claim which Dublin can have to be considered as an architectural city depends mainly on GANDON's works. Their importance is so prized among the discontented exiles from Ireland in America, it is difficult to gain belief for the fact that they were designed by an Englishman, and one, too, who was a Huguenot by descent. It is commonly believed they were the works of Celtic architects. Indeed, there would be less opposition at the present time to the proposed enclosure of an arcade in GANDON's Custom House if it were known that its origin is to be credited to a stranger. GANDON was, however, only one among numerous English architects that from the time of the Invasion—seven centuries ago—devoted their talent to the adornment of Ireland.

Any impartial judge who considers the Custom House and the Law Courts (Four Courts), which stand by the side of the Liffey in Dublin, is likely to conclude they were designed by a man who by nature was endowed with constructive ability. And yet if it had not been for a reverse of fortune it is not unlikely that GANDON would never be included among the architects of the eighteenth century. He was born in London on the last day of February, 1742. GANDON early displayed a love of art, which was not a common weakness among young gentlemen in that age. When, owing to various misfortunes, it was found that his father could not provide an adequate income for him, young GANDON was wisely advised to be guided by his predilections. He joined the old Academy in St. Martin's Lane, and evidently he profited by the teaching, for in his fifteenth year he was able to gain a prize offered by the Society of Arts. About the same time WILLIAM CHAMBERS, who, although only twenty-nine, had gained much experience on sea and land, returned to London, and had resolved to set up as an architect, his first commission being the improvement of Kew Gardens. GANDON was able to gain employment from him, for CHAMBERS, knowing the English weakness for novelties, had resolved to tempt fortune with designs for buildings in the Chinese style, and he was likely to prefer a clever novice as assistant before one who had gained experience in the Classic style which then prevailed. Subsequently, when CHAMBERS's prospects of success as an architect became more assured, GANDON became his articled pupil. In his twenty-third year GANDON commenced practice as an independent architect. After the example of his master, his practice included the production of architectural books. In connection with JOHN WOOLFE he brought out the fourth and fifth volumes of the "Vitruvius Britannicus." Their respective shares are not to be ascertained, but apparently the greater number if not the whole of the plates were drawn by GANDON, and many of them were engraved by him.

Although a member of the Free Society of Artists, GANDON could hardly be opposed to the Royal Academy, which was founded mainly through the efforts of CHAMBERS. He was rather young to be included among the associates, and as a professional architect he could hardly care to be accounted a student. As was to be expected, the province of the Academy was not then fully defined, and the duties of the professor of architecture, which were confined to the delivery of six lectures, were mainly intended for the instruction of painters who might have to introduce buildings into the backgrounds of pictures. The offer of a premium for architecture, the subject being *A Triumphal Arch Commemorative of the Seven Years' War*, amazed GANDON. He says he was electrified. He ran off to consult PAUL SANDBY, who was one of the Academicians, and was informed that he was ineligible, for the competition was restricted to students of the Academy. GANDON immediately entered his name as a student, and apparently no more was required than to attend the lectures of the various professors in order to become qualified. In due time he was

awarded the gold medal. But before surrendering it the Academicians wished to impose another test. All the students of the architectural class were asked to submit impromptu designs, the subjects being determined by lot. An ornamental entrance to a park fell to GANDON, and his design was considered even more satisfactory than his triumphal arch. Sir WILLIAM CHAMBERS expressed satisfaction on finding his pupil so early distinguishing himself. It was probably no great victory, for GANDON's opponents were not able. But some interest must always be attached to the first winner of the medal. In the same year he responded to an advertisement from the merchants of Dublin, and submitted a design for a Royal Exchange. The first premium was awarded to THOMAS COOLEY, who was also an Englishman. GANDON received the second premium, and we need hardly say he was confident that to private interest the victory of his rival was due. He was successful in another competition for the new Bethlehem Hospital, a London work; but he was hardly more fortunate than in Dublin, for he was not entrusted with the erection of the building.

The neglect of GANDON, who was not offered many commissions for buildings during some years, may be explained by the difficulty which was found by the public in separating an architect's work from a builder's. CHAMBERS, although patronised by the Court, designed few buildings, and they were ordered by a special class of nobles. GANDON was less likely to be patronised. He had serious thoughts of abandoning England and accepting an invitation of the Princess DASHKOF to practise in Russia. In 1779, however, it was decided to erect a new Custom House in Dublin, and as GANDON's design for the Royal Exchange had attracted the notice of JOHN BERESFORD, the commissioner of Customs, he was requested to undertake the work. BERESFORD belonged to a pugnacious family, and apparently in making arrangements for the new building he enjoyed himself by ignoring all the rights of proprietorship which were attached to the site. The Corporation considered the ground belonged to the city, and as they were most loyal there would be no difficulty in arranging with them. But that course appeared absurd to BERESFORD, who was in all things an autocrat. Accordingly, after consulting GANDON, the Commissioner persuaded the Government to leave the affair in his hands. In the beginning of 1781 BERESFORD considered the time had arrived to start operations, and the following epistle which he sent to the architect will suggest the extraordinary strategy which was then adopted in dealing with public works in the Irish capital:—

Dublin: January 15, 1781.

Sir,—I have the pleasure to inform you that I have at length obtained an order from Government for the building of a new Custom House, with all possible expedition, and I have proceeded so far as to send to take possession of a large lot in the lower situation. I expect to accomplish this in the course of this week, and the sooner afterwards we can settle our plans the better. This business must be kept a profound secret as long as we can to prevent clamour, until we have everything secured.

Our first step will be to wall in the ground as soon as we shall get possession of it. This will discover us, and the clamour will then be made that there will not be sufficient room for shipping; to answer which, it will be right to have our plans for the new docks ready, to show the people how well they will be accommodated.

I therefore request you will turn your thoughts immediately to that subject, and, as I hope, we may hereafter claim you as our own, that you attend to us in the first instance, as the business is of a delicate nature, and must be managed still with dexterity, having the city of Dublin, and a great number of the merchants, together with what is considered as the most desperate of the mob, to contend with on this side of the water, and also some persons of high interest and weight on your side, who will make use of every exertion to prevent us.

However, a Custom House must now be built, so we shall now expect you, and I must beg to know when you think you can come over.

We shall wall in and carry on the dock as soon as we can, and the plans for the building may be adjusted during this period. I would recommend it to you to come by Liverpool by all means, as you will then see their docks, and procure every information about them. Let me hear from you immediately.—

I am, sir, your humble servant,

JOHN BERESFORD.

James Gandon, Esq.

It is manifest from what Commissioner BERESFORD wrote that the Government could have no title to the ground required for the building, docks and the other works which he contemplated. The letter suggests the indifference to law and equitable considerations which inspired officials in those days, and by which the loyalists of Ireland were estranged from the Government of their country. The Corporation invoked the interference of the judges, who decided against the Government. The people were only too glad to have a share in the contention between the imperial and municipal authorities, and the hoarding was thrown down with the acquiescence and in the presence of the High Sheriff. That was on a Saturday. BERESFORD was in his glory. He gave orders that on the Sunday the hoarding was to be again set up, and he advised GANDON to prevent all opposition and to "laugh at the extreme folly of the people." GANDON was inflamed by the combativeness around him. He resolved to bear a part in the scrimmage. He wrote: "Having been in early life a good swordsman I am determined to defend myself to the last." We suppose the mob could not fail to admire so much courage, and they may have thought that the works could never be carried out on so unsuitable a spot.

Generally, ground beside a river is a difficult place on which to erect heavy buildings. In Dublin there are geological peculiarities along the Liffey. About thirty years ago it was necessary to take down a large goods store which formed a railway terminus before one ton was placed on the floors. The site was not far from the Custom House. Careful boring was undertaken before the store was started, and it was ascertained that a bed of the hardest gravel existed at a certain depth below the surface. The foundations were carried up from it, but it succumbed under the weight, and then it was discovered that the ordinary geological arrangement was reversed, for the hard gravel was a mere covering to a bed of soft peat.

GANDON found he had to deal with an enemy that was not to be scared with a cane sword. For the north side and wings there was no difficulty in obtaining a secure gravel foundation, but with the south front adjoining the river it was otherwise. The great cupola which gives so much character to the building was also to be provided for on a soil of which water appeared to be the principal constituent. GANDON was without the aid of such pumping machinery as can be now obtained on moderate terms, and the endeavour to oppose the power of a navigable river by scoops and hand-pumps is too interesting a feat to be described in any words but his own. He said:—

The labourers had scarce got down 2 feet below the surface when they came to water, which four men emptied with scoops as they continued to extend the line of trenches, which were carried on in short lengths, and, for convenience, of different depths. It became necessary to make dams across parts of them with sods, and to empty the water from the lower to the higher dam, until it was at last sent off in a drain prepared for that purpose, our pumps not being then ready. The ground was opened first at the north and continued round to the east front; then to the south end, where a boiling spring with sand appeared at about 4 feet below the surface, which filled up as fast as it was cast out. It extended for a considerable distance. Inch and half sheeting piles, about 7 feet long, were driven down with a maul to keep up the bank, and sods were fitted in layers between it and the piles, which prevented the sand from being washed out, thereby enabling the men to clear out the trenches to the depth required. The general texture of the ground was gravel, mixed in some places with a layer of blue clay and sand, under which was a hard strong gravel. When the trenches were thus prepared and cleared out, the rough masons then proceeded to carry on the first bench or course with all possible expedition with the black stone, and immediately filling in with earth, in order to give less water to the pumps. In the meantime another length, and of the same depth, was got ready, and an additional number of masons set to work. In this manner the whole was continued until all was brought up to the level of the ground.

The quay wall or road on the south front was an old embankment, made about the year 1725. It was 60 feet wide at top and badly constructed; the walls of black stone; its foundation laid on the surface of the strand. On the side next the river it was 12 feet high, but on the inside only 8. The filling between the walls was a sand used for ballast. The base of the foundations stood at least 6 feet above the bed of the river; the tide not only soaked under them, but filtered in several places through the joints of the masonry. It was

therefore deemed most prudent to commence with the north-east wing, after the portion of the store-room, it being less liable to be incommoded with water from the river.

Directions were now given for excavating that part of the centre of the south front for the cupola and portico, and as this advanced so near the river we were certain of much obstruction from the flowing of the tide, which was the only water that now gave us any trouble, for the springs were now pretty well dried and kept under. The pumps hitherto used were but 13 or 14 feet; we now used two of 18 feet in length. As the ground altered in its texture towards the river, becoming more loose, with small sandy gravel, like that of the south-west angle, to which depth we had sunk, we deemed it prudent to bore it in several places which were near the angles of the front of the portico, but particularly where the walls of the cupola were to be erected, to the depth of 8 feet below the then surface, and it appeared to be much of the same substance as that already described. A pile, 10 feet long and 1 foot square, was driven down in the centre to 9 feet depth, but after twenty strokes of the ram it could be driven no further, which assured us that we had got down to firm ground.

Upon consulting with the principal artificers on the spot, it was thought advisable to desist from sinking any more, but to make an artificial foundation, in order to sustain the great weight of the cupola; but whether by piling or otherwise was submitted wholly for my consideration. This part of the work had long occupied my thoughts, and to it I had given every attention, my conjectures having led me to expect great difficulties on this subject. I had nearly made up my mind as to the means I should adopt, and was the more strongly confirmed in my intentions, having remarked a circumstance which escaped the notice of those around me. Immediately after the pile had been driven I perceived a small stream of water arising up close all around it, as if it had pierced a spring; and recollecting an observation in Labeyle's account of Westminster Bridge, "that piles sometimes loosen and open fresh springs, which often make it very difficult to get rid of the water," I was now apprehensive of just such an impediment. The great expense of preparing the piles, and the very long time it would take to drive so great a number as would be required presented a strong objection to the use of them. I therefore gave directions to have a grating of Memel timber prepared, the timber to be 1 foot square, to have the upper ones notched down 3 inches in the ground pieces, which were to be bedded on a layer of cut heath, the whole ground being first correctly levelled; the interstices of the grating to be filled in with hard sound stock-bricks up to the level of the timbers, swimming in mortar composed of pounded roach-lime and mortar well mixed, which answered nearly as well as tarras; over which was laid 4-inch fir plank fastened down on the grating with oak trennels, which was all completed. The foundation-walls were then set out on September 17. The part directly under the cupola was laid with rough blocks of mountain granite in regular courses; in the first course was sunk an iron chain of flat bar 4 inches wide and 2½ inches thick, into collars which were run with lead, but the bars were only covered with a cement of wax, resin and stone dust. The rest of the foundation was done with the usual black stone and was carried up to the plinth by October 16, 1782, thereby completing the whole of the foundations in one year and four months from the opening of the ground.

The authorities should have respect for a building which exemplifies so marked a victory over physical obstacles. From its character as well as its position it cannot be enlarged, but to block up the open arcading of the south front will be an act which must be deplored, for it means a debasing of the building. If a general transformation took place, it would form a less hideous spectacle than will be the consequence of the official proposals. The Custom House is a masterpiece which would impart dignity to any city in Europe. It will bear a comparison with the chief work of GANDON'S master, although it was erected with a more limited sum of money. The effect of adaptation can be judged in Somerset House, and the opinions which have been expressed about that experiment should be enough to compel the Government to hesitate before committing a second blunder. In Dublin the effect will be more hideous, for the alteration will be equivalent to destruction.

The next work on which GANDON was engaged was the Parliament House, now used as the Bank of Ireland. He was commissioned to carry out alterations which were probably intended to conceal the impending fate of the building, for as the Union with England was decided on there was not much use in expenditure to provide a special entrance for the Peers. Although without height the Parliament House is an impressive building. But when GANDON was called in it was less attractive than it is now.

It possessed the colonnades which unite to form the principal feature, but as the building stood between private houses on the east and west sides, it could hardly be considered as complete, and seemed to be a sort of screen to something which, in order to see it properly, the spectator must stand elsewhere. The genius of the unknown designer appears more remarkable if we consider the restrictions imposed on him, by which he was practically limited to the forming of a passage around three sides of an open court to a building which was almost concealed from view. GANDON's duty was to remove the adjoining houses and to substitute lateral porticoes. The Ionic order was adopted in the original structure. On the eastern side, in which a special entrance to the House of Lords had to be formed, he decided to employ the Corinthian. It is popularly supposed that the variation was dictated by the peers, who assumed that their dignity would be suggested by the superior order. But GANDON may have discovered that, owing to the difference of levels, he could not employ Ionic columns of the same dimensions as those in the colonnades; he would be forced to impart more height to them, and, as the lesser of two evils, it was therefore preferable to set up a Corinthian portico. The contrast between the two styles is more apparent than was contemplated by GANDON, for the banking company added several Ionic three-quarter columns in order to insure the unity of appearance which was considered desirable. The western side of the building was also much altered afterwards, and GANDON cannot be held responsible for it. There is now an Architectural Association in Dublin, and the members could usefully employ themselves in the preparation of drawings which would suggest the various changes of the building.

At the Parliament House GANDON had to take up the work of a great architect, whose name remains unknown. In his next commission he was to complete the Law Courts, which were commenced by COOLEY, his successful rival in the competition for the Exchange, and who died in 1784. The group of buildings, like the Custom House, is on the side of the river. The quadrangles were already erected, and for all we know to the contrary the planning of the central part was to some extent arranged by COOLEY. However, the circular hall and the courts are supposed to be GANDON's work, as well as the dome above the hall, the portico, &c. But in this case also there was a conflict of authority, and in consequence GANDON dared not realise his intentions. After the laying of the first stone by the Lord Lieutenant, and before the crowd had dispersed, a travelling carriage arrived containing a gentleman whose name GANDON does not mention, but as he describes him as having "considerable fortune and influence, a privy councillor, and a member of the Irish Parliament, from whom, on my first arrival in Ireland, I had experienced considerable attention and hospitality," there is little doubt it was BERESFORD. In an uncourteous tone the mysterious stranger demanded to know what was going on, why the quay was enclosed, &c. "I informed him," records GANDON in his diary, "of the reason for enclosing the ground, and stated that, as the architect, I was no way responsible for the situation of any public building, but merely acting as a professional man, employed by Government, had been requested to make designs for new Courts of Law, adjoining the law offices which had been previously erected. I stated I had submitted my designs to the Lord Lieutenant, who, with the Lord Chancellor and chief judges, had, on consideration, approved of the design and had given directions for the building to commence." But the stranger was not to be satisfied, and declared that if the building proceeded it should be pulled down. GANDON consulted Lord PORTARLINGTON, and was advised to set back the portico; but, as he says, "even this sacrifice of my design was not sufficient, for as the gentleman had not been consulted about the building he disapproved of the designs, which he condemned in every particular, stating the most singular objections." In its new position the portico was valueless, and conveyed the notion that it was only one among several shams.

The position of the Law Courts in Dublin could not be defended, and the reason for the selection of such a site is not easily discovered. But when the courts were erected it would be reasonable to conclude that lawyers would con-

gregate in the neighbourhood. Once more perversity prevailed, and it was decided to erect "the King's Inns," or substitute for the "Temple" in London, at a more remote distance from the centre of the town. GANDON obtained the commission, and although his building is rarely seen by visitors to Dublin, for it stands in a wretched quarter, it is an interesting example of architecture. Additions have not improved it, but the original façade to the garden shows skill in composition. GANDON had discovered an Irish sculptor named SMITH, and in order to utilise his talent he flanked the entrance to the dining-hall with figures of Plenty and a Bacchante as caryatids, while at the corresponding entrance to the Prerogative Court Security and Law appear. There are also reliefs of Queen ELIZABETH presenting a Bible and a charter to the Irish lawyers and prelates, Wisdom, Justice and Prudence offering one sort of sacrifice, and Bacchus and Ceres offering another. Architectural ornament is liberally introduced within and without.

GANDON was supposed to be competent to direct all kinds of construction in stone, and when a new bridge had to be erected, the commission came to him as a matter of course. It was known as Carlisle Bridge, but a quarter of a century ago it was removed as it was not equal to the increased traffic, and a wider and more level bridge was substituted.

GANDON was too shrewd a man and too closely connected with the Government to be indifferent to the perils which might arise to a stranger who could be made responsible for the errors of those in authority by ignorant people. The coming events of the Rebellion were casting their shadows, and the architect considered it was wiser to leave the King's Inns unfinished and to seek safety in England. There he remained for two years. On his return he found there were more changes than he had anticipated. The operations which were needed to bring about the Union did not sweeten the official temper, and the lawyers who were uncertain about their future were glad to utilise the incomplete King's Inns as an excuse for grumbling. Money for the works was doled out grudgingly. GANDON endured his fate as well as he could, but when at length the Lord Chancellor, who was an Englishman, joined the discontented critics, he was compelled in self respect to resign all his appointments. But he had become attached to Ireland, and having purchased a small estate at Lucan, a few miles from Dublin, he lived there until 1823. It is believed that by his desire he was buried in the grave in which his old friend FRANCIS GROSE, the antiquary, was lying for thirty years, the "dainty chiel," the "fine, fat, fodge wight, o' stature short but genius bright," beloved by ROBERT BURNS, and who, after so many drinking bouts, had fallen a victim to Irish conviviality.

#### COST OF ELECTRIC LIGHTING FROM PUBLIC AND PRIVATE SUPPLY.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

THIS subject has, of late, been brought into prominence by inquiries in the electrical journals; and as I have had several cases to consider, and at present have the matter before me, advising with reference to a private installation at a large institution, it may be of interest to republish some curves which I recently prepared, showing the cost of electric lighting from supply mains and from a private plant, in order to show clearly when it is approximately advisable to adopt a separate plant.

In these curves gas-engine plants of less than 50 horse-power have been considered, and they will not apply to a much larger plant.

In their preparation assumptions have been necessary, and they are given in full, but they may be altered, and the curves will not lose their value owing to any uncertainty as to the kind of assumptions made.

The charge for attendance has been taken as 20s., plus 2s. 15s. 6d. per kilowatt installed; or, what is the same thing, 20s. plus 20d. per lamp on at one time per annum; where plant is provided for the whole of the lights to be run at one time, and where 15 units per 8 candle-power lamp per annum are consumed.

An amount equal to 10 per cent. of this is added where plant is provided for half the lamps on at once, and 20 per cent. for quarter-lamps on at once. The charge for attendance is 20 per cent. higher when 30 units are used per 8 candle-power lamp per annum than when 15 units are used.

The capital expenditure on plant and works has been taken as follows (including accumulators) :—

Kilowatts installed.	£	Kilowatts installed.	£
1.2	240	9.0	600
2.4	300	18.0	950
4.5	420		

The interest on the capital, and depreciation and repairs have been taken together as 10 per cent. of the outlay per annum.

The charge for oil and stores is taken at 2 $\frac{1}{2}$  ros. per kilowatt.

The gas consumption is taken to be as follows :—

Kilowatts installed.	Cubic feet per unit.	Kilowatts installed.	Cubic feet per unit.
1.2	56	9.0	42
2.4	53	18.0	32
4.5	49		

Price of gas—2s. 6d. per 1,000 cubic feet.

The plant estimated for does not include any reserve with the exception of the accumulators, as it is assumed that there is a connection with the supply company's mains. It has been questioned whether a supply company, or local authority, can be compelled to make a connection. I am of opinion that the undertakers under a provisional order must make a service connection for any applicant

within the area of supply, and cannot demand a guarantee to pay for any fixed quantity per annum beyond that allowed by the provisional order, if the applicant bears the cost of the connection.

The cost of running the private plant has been taken to be the sum of:—

Interest on capital, depreciation and repairs, cost of attendance, oil, stores, &c., gas, accumulator renewals (at 10 per cent. per annum), and rent of gas meter.

The cost for current only, from supply mains, is compared with the above. All expenses which are common to both, such as wiring, fittings, &c., have been excluded.

#### Explanation of Curves.

The horizontal ordinates show the number of 8 candle-power lamps (30 watt) installed, the vertical ordinates the cost per annum.

The thin line curves refer to current from supply mains, and the price per unit is marked on each.

The thick line curves show the cost for current when a separate plant is provided.

The full thick line shows cost when plant is provided for all the lamps to be running at once. The line dotted - - - - shows cost when plant is provided for half the lamps to be on at once, and the line dotted — . — . shows cost when plant is provided for quarter-lamps to be on at one time.

The curves on diagram 1 are worked out on a basis of 15 units per 8 candle-power lamp per annum, and those on diagram 2 for 30 units per 8 candle-power lamp per annum.

*Example 1.*—To find the least number of lamps which can be economically worked from a private plant where current can be obtained at  $4\frac{1}{2}d.$  per unit.

It is evident that a line drawn representing the cost of current at  $4\frac{1}{2}d.$  per unit (see thin dotted line) will cut the thick ones at three points on each sheet :—

## DIAGRAM 1.

15 units per annum.

- (a) All lamps on at once, about 1,200 lights.
- (b)  $\frac{1}{2}$  lamps on at once, about 725 lights.
- (c)  $\frac{1}{4}$  lamps on at once, about 410 lights.

## DIAGRAM 2.

30 units per annum.

- (a) All lamps on at once, about 435 lights.
- (b)  $\frac{1}{2}$  lamps on at once, about 270 lights.
- (c)  $\frac{1}{4}$  lamps on at once, about 170 lights.

It is also evident that these numbers of lamps can, under the different conditions, be run at the same cost by either method.

The highest estimate is 1,200 lamps, and the lowest comes out at 170 lamps of 8 candle-power. This result explains to some extent the widely different results given by different experts to the same question in the *Electrical Review* of December 25, 1896.

If, however, the units consumed per 8 candle-power lamp per annum and the maximum number of lamps usually required at once are specified, the number of lamps can be given accurately. Suppose 22 units are used per 8 candle-power lamp per annum, and that half the lamps are required at once, then the number is the mean of the two, line (b), i.e. 725 and 270. Result, 500 lamps (approximately).

Owing to the anxiety caused by a private plant I should say that, under the above conditions, it would pay to lay down a private plant if there is an equivalent of 600 8 candle-power lamps connected.

In any case, where the units consumed are less than 15 or more than 30 per 8 candle-power lamp per annum, the method here described, of taking proportional parts, will not apply, and the problem must be worked out separately.

*Example 2.*—To find the annual saving by running a separate plant for 400 8 candle-power lamps, using 30 units per annum each (or about 1,000 hours burning), where a supply can be obtained at  $4\frac{1}{2}d.$  per unit.

Referring to diagram 2, thin dotted line, the cost of current is 225*l.* The cost, if a private plant is used, is (a) 233*l.*, (b) 189*l.*, (c) 155*l.*

Thus there would be no saving if plant is provided for all the lights at once, 37*l.* per annum if plant is provided for half the lights at once, and 70*l.* per annum if one-quarter of the lights are provided for at one time.

If the number of units is between 15 and 30 per 8 candle-power lamp per annum, proportional parts may be taken between the results of diagrams 1 and 2, as in the last example.

It will be noticed that the ratio of the plant provided to the total number of lights has a very great effect on the point when it will pay to provide a separate plant. It is not necessary to instal plant sufficient for the greatest number of lights ever on at once. The plant can be laid down sufficient for the usual maximum; rock-over switches can be placed on each sub-circuit, so that one or more circuits can be switched over to the mains in case of an abnormal load, or in case of any breakdown of the plant. These rock-over switches could also be used at times of fairly light load, when the demand is too low to warrant the starting of the engine, and when it is too heavy for the accumulators to undertake.

The points which I wish to emphasise are :—That the units consumed per 8 candle-power lamp per annum, and the usual maximum demand have a great deal to do with the question of when it will pay to instal a separate plant, and that, unless these figures are known, no answer can be given to the question.

In conclusion, it must not be imagined that these curves are intended to take the place of the advice and assistance of a consulting engineer, as there are many special conditions, considerations and questions which cannot be introduced into a curve; but I think they will prove of value (if the assumptions are studied carefully before the results are taken for granted) to architects who wish to know when (given ordinary circumstances) it will pay to put

down a separate plant. They will be even more useful to those who wish to see what effect the varying of the units consumed per lamp and also of the maximum demand has upon the point when it will pay to discard the public supply.

I am greatly indebted to the editors of the *Electrical Review* for their permission, kindly granted, to reproduce this article in its almost original form.

## EDINBURGH ARCHITECTURAL ASSOCIATION.

THE next visits of the session take place on Saturday, April 24, and (by kind permission of Mr. Charles Gulland, commissioner for Mr. George Johnston, of Bavelaw) will be to Bavelaw Castle, which is beautifully situated on the northern slope of the Pentlands, about two miles from Balerno Railway Station. It is of seventeenth-century date, on the L plan, with a small additional wing at the south-east angle. The kitchen has a fine arched fireplace and window adjoining. The entrance into a wheeled staircase is on the east side. The elevations are characteristic of a Scottish house of a late date. There is, too, Lennox Tower, situated about one mile west from Currie, on the summit of a lofty ridge on the right bank of the Water of Leith. It has been an important structure and of great strength, is isolated on all sides and surrounded by extensive earthworks. The main structure is an oblong keep, measuring 57 feet by 33 feet 2 inches, with walls about 7 feet 6 inches thick.

## GOTHIC ARCHITECTURE.

SIR JOHN SOANE used to tell students of the Royal Academy in his lectures emphatically that Gothic architecture was anything that was not Grecian. Wren unfortunately called it "a gross concameration of heavy, melancholy and monkish piles." But Wren was blind to the beautiful details of Gothic architecture, although he appreciated those of its scientific construction and its general forms, as his well-known reverence for King's College Chapel, Cambridge, which he declared to be inimitable; and his clumsy imitation of York Minster in his west front of Westminster Abbey; his pseudo-Gothic of St. Mary, Aldermary; his almost beautiful imitation of Magdalen Tower, Oxford; in that of St. Michael, Cornhill, tacked, by the way, to a Doric interior; and his singularly beautiful spire of St. Dunstan-in-the-East, although disfigured by Roman mouldings, abundantly testify. Nor must the Gothic construction of some of the concealed parts of St. Paul's Cathedral be omitted in this category of Wren's blindness to the beauty of this style, or of his willingness to be taught by such an enemy to the taste he revered. It is painful to speak thus of a man like Wren, but his fame as a mathematician, and as the greatest constructive architect that England has produced, besides his many other eminent qualities in the highest branches of learning and science, will more than counterbalance this defect, although not a small one. Another architect has declared that Grecian, Roman, Byzantine, or such like architecture used in ecclesiastical edifices is Pagan and unchristian; as did Taylor the Platonist declare, in as dictatorial a manner, that all who did not believe in the religion of the Platonist school were infamous, daring and Galilean. What says the anathematiser of Pagan and unchristian edifices to the "Pagan and unchristian" style of the cathedral of the Christian world, or the beautiful Christian churches of Michel Angelo, Raphael, Bramante, Palladio, Scamozzi, and other Christian architects of the Medicean period of Italian art? William Hazlitt justly compares the correctness and chastened rules of Grecian architecture to those of the Greek tragedians, and the elements of its style to the purity of their incomparable language. "A Doric temple," observes this discriminating critic, "differs from a Gothic cathedral as Sophocles does from Shakespeare." The principle of the one being simplicity and harmony, governed by severe rules; that of the other richness and power, directed more by fancy and taste than by too rigid an observance of scholastic discipline. The one relies on form and proportion, the other on quantity and variety and prominence of parts. The one owes its charm to a certain union and regularity of feeling, the other adds to its effects from complexity and the combination of the greatest extreme. The Classical appeals to sense and habit, the Gothic or romantic strikes from novelty, strangeness and contrast. Both are founded in essential and indestructible principles of human nature.

New Sunday Schools which have been erected in connection with the Castlemere Chapel, Rochdale, were opened on the 15th inst. The schools, which will accommodate 700 persons, have been erected at a cost of 3,500*l.*

## NOTES AND COMMENTS.

It is not satisfactory to learn that the finances of the University of Cambridge are in such a state the new buildings which are so urgently demanded cannot be erected. According to a correspondent of the *Times*, who evidently writes with authority, "More space is urgently needed for the University Library; the School of Law is without a home, though a site for one is available; lecture-rooms are wanted for classics, history, philosophy, languages, music and other subjects; the executive officers of the University are without suitable offices; for many examinations rooms have to be hired in the town, and the antiquarian and ethnological collections are robbed of a great part of their usefulness by the want of a proper museum." It cannot be said that the authorities of the University are indifferent to the necessity of suitable buildings, for the greater number of the museums and laboratories which are to be found in Cambridge were unknown thirty years ago. Nor is the deficit owing to the greed of Fellows. In seventeen colleges the corporate income has been diminished by 35 per cent.; in only two colleges can the full fellowship be paid, while in some what is received is no more than a third of the normal amount. There are endowments for specific purposes, but it appears the free endowment revenue of the University is considerably under a thousand a year. The colleges are expected to contribute to the University expenses. On the basis fixed in 1877, it was anticipated that last year the amount would reach 30,000*l.*, but all that was paid was 22,000*l.* The demand for more expenditure arises from the inadequacy of the buildings. Efficiency is now maintained by self-sacrifice on the part of teachers, but that strain cannot always be endured. Cambridge is essentially the representative of modernism, and if it is to keep pace with the advances of science there must be outlay which will enable it to compete with foreign universities. How that end is to be attained demands the attention of all who wish to see England hold its own in the highest educational planes.

THE completion of the Pont Alexandre III. in Paris will be watched with much curiosity, for an effort is to be made to produce a steel bridge which will be a work of art. Two architects, MM. CASSIEN-BERNARD and COUSIN, are co-operating with the engineers, MM. RESAL and ALBY, to that end. At each extremity will be two pylons formed of four columns of white marble, rising to a height of 20 metres, which will bear bronze figures of "Renown;" at the bases, for which Finland granite will be used, there will be figures of France and Russia in war and peace. In front of the pylons will be pedestals with figures of Victory. The balustraded parapets will be in wrought copper and bronze, terminating in figures suggestive of the branches of the Seine. There will be twenty-eight figures of white marble carrying lamps on the superstructure, and in the centre an immense number of electric lights forming a constellation. The steel arch will be partly gilded, and with the marbles and bronzes it is expected a colour scheme of extraordinary richness will be realised.

THE Americans are congratulating themselves on the completion of the Congressional Library in Washington, and if we consider how well sculpture and painting are made to subserve architecture in it the building is deserving of all their admiration. There is, however, one stigma upon it which must diminish its interest in the eyes of architects at least. In an elaborate description by Mr. ORVIS, published in *Architecture and Building*, it is explained that the architects, Messrs. SMITHMEYER & PELZ, "received practically no commission or pay for their work, on which they had been employed for over twelve years." After their appointment the architects, in order to facilitate arrangements, accepted salaries instead of advances on the advice of the chairman. But from the time the works were commenced the Congressmen meddled with the operations, and eventually the control was handed over to an officer of engineers, for in the United States as in England the sappers and miners are always prepared to undermine an architect's position on public works. Mr. SMITHMEYER

resigned, but Mr. PELZ was allowed to remain, as without him the working drawings could not be prepared. After three years he was also superseded. Messrs. SMITHMEYER & PELZ then claimed 2½ per cent. on an estimated outlay of 7,000,000 dols. At the trial several of the most prominent architects gave evidence in support of the claim, while not one could be found to testify against it. Instead of 170,000 dols., the Court assessed the damages at 48,000 dols., ignoring the evidence that the outlay amounted to a much larger sum. Circumstances compelled the architects to accept the money, and after the expenses of the lawsuit were paid they found there was left a sum which was "scarcely a sufficient equivalent for the services of a third-rate draughtsman." The indebtedness of America to them for an able work is ignored, and the credit appears to be given to others. Mr. ORVIS says "That they are this day still obliged to fight for their own, and will in all likelihood be compelled to do so, no one knows for how long, fills all who know these facts with sympathy," and in that sympathy Messrs. SMITHMEYER & PELZ can be assured English architects will not fail to join.

A SANITARIAN who visits the palace of Versailles should never inquire about the arrangements in which he has interest. In its palmy days it possessed only a single bath-room, which was never used. A colossal "vasque" of marble was placed in one of the corners of the building, but neither the Grand Roi nor one of his marshals could attain the courageous mood that was necessary in order to bathe in so much water. As the marble bath was useless, Madame DE MONTESPAN asked for it, and LOUIS XIV. was glad to be rid of so unnecessary a superfluity. It was placed as an ornament on the lawn of her property, the "Ermitage," and there it remains.

A SPECIAL committee of the Society of Beaux-Arts Architects in the United States have recommended the following conditions as essential to the fair and orderly conduct of a competition:—*a.* That a professional adviser shall be appointed by the party instituting the competition, whose duty it shall be to assist in the preparation of the programme, to assume all the direct relations with intending competitors, receiving and answering all communications, and giving all information in writing to all intending competitors alike; to examine all drawings or other matter called for by the programme, and place out of competition and return unopened any that do not conform to the terms of the programme; to make a selection of one or more designs, as the programme may direct, and to submit his selection, together with his reasons therefor, to the parties instituting the competition. *b.* If the proposed work is of sufficient magnitude, a jury of award of three experts should be put in charge, to consist of the professional adviser of the party instituting the competition, an architect nominated by a vote of the competitors, and a third, also either expert architect, and chosen by the other two. This jury to have the same duties and powers as above given to the expert adviser. *c.* A standing committee of experts, so chosen as to represent the various architectural societies, and exercising the duties of the jury, would give even greater guarantees of fairness and impartiality, and members of this Society are urged to use their influence towards bringing about such united action on the part of other societies as would enable competitors to ask for such a jury. *d.* The author of the best design to be appointed the architect of the work, with privilege on the part of the party instituting the competition of having a consulting architect without additional charge to them. *e.* The architect of the building to receive at least the rates of compensation established by the schedule of the American Institute of Architects. *f.* The programme to be full and explicit on all the above points, and, besides, to fix a definite time and place for the receipt of drawings, fix an exact limit of cost if practicable, give all useful or necessary information as to lot and surroundings and as to requirements for occupancy, fix the number, scale and character of drawings, give essential details as to construction and materials, and prescribe definite limits regarding descriptions, estimates, &c., which shall accompany the drawings.

CATHEDRAL SERIES.—SALISBURY: NORTH CHOIR AISLE.

ADDITIONS TO STADACONA, STAMFORD HILL.

THESE additions, as will be seen from the plan, comprise the professional portion of the residence of Mr. THEO. HOSKIN, J.P., M.R.C.S., &c. The house is in Amhurst Park, Stamford Hill, and has been considerably altered as well as added to, the principal internal alteration being the formation of a large hall in the centre of the house, by the removal of a small room and lobby, &c., which were of no importance. The additions are carried out externally in red brick, to correspond with the existing house, and the roof covered with Broseley tiles, the old roof being also tiled. The moulded work to chimney-stack and window sills, &c., is of Portland stone. The porch, windows, bargeboard and eaves cornice are of wood, painted white. Internally, the principal features of the waiting-room and consulting-room are the ingle-nook fireplaces and the bay windows with fixed seats. The floors of the additional portion are of wood blocks, stained to match the woodwork, that in the consulting-room and dispensary being "palm-leaf" green, and the waiting-room "American walnut" colour. The other woodwork in the halls, staircase and corridors throughout the house is painted white, and the doors red, the darker tint of De Morgan lustre tiles, from which the colours of the paper are copied. The chimney-pieces for the new rooms and the new hall were supplied by ALDAM HEATON, the grates by ELSLEY & Co. and STEEL & GARLAND, the fireplace tiles by DE MORGAN & Co., and the slips and fenders are of antique marble. Mr. T. W. RHODES, Stoke Newington, was the builder, and Mr. LOUIS AMBLER, A.R.I.B.A., 7 Arundel Street, Strand, the architect.

THE WEIDEMANN MEMORIAL, BROMPTON CEMETERY.

THIS monument was erected rather more than a year ago by Mr. F. J. WEIDEMANN, in memory of his wife. It is executed in white statuary marble. The whole of the carving is symbolical, and the ornamental work representative of the favourite objects and tastes of the deceased, this latter work being carried out in sunk carving run with lead in the panels at the back of the monument. The full-size detail drawings of the carving were made by Mr. WEIDEMANN. The memorial was carried out by Mr. EDWARD LANDER, monumental mason, of Kensal Green, the carving being executed by his assistant, Mr. J. SWAINE. The architect was Mr. LOUIS AMBLER, A.R.I.B.A., of 7 Arundel Street, Strand.

STREATHAM CEMETERY.—THE CHAPEL.

## LIGHTHOUSES.

By ALFRED J. GLASSPOOL.

*(Concluded from last week.)*

THE method adopted in building a lighthouse depends on the nature of the soil upon which it is constructed, and also as to the character of the sea fight to which it is exposed.

If the lighthouse is to be built upon a sandbank, six or eight iron cylinders are grouped so as to form a hexagon or an octagon. These are "joined to piles screwed or forced in some other manner to a considerable depth down into the sand, the piles and cylinders being braced together by strong iron ties. Upon a skeleton structure of this kind is built the lighthouse, the living rooms for the keepers, surmounted by the lantern." We may see four of these lighthouses off the coast of Essex: they are the Chapman, the Mucking, the Maplin and the Gunfleet. Though slim in appearance, these constructions are in reality very strong, for the waves pass through them with little obstruction; the Maplin has stood the test for over fifty years.

Mr. Edwards, in his excellent little book, declares that the oft-repeated statement that there is some analogy between the construction of a lighthouse and the form of a tree is altogether wrong, though he does not deny that Smeaton gained his idea for the construction of the Eddystone by contemplating an oak tree. He gives us a concise idea of the form of a lighthouse in the following words:—"A number of horizontal conic sections or frustra with varying diameters, placed one upon another in

such a manner that the vertical outline of the tower forms a curve convex to its axis, commencing at the radius of the base and ending at the radius of the top, the curve being made to approach parallelism with the axis towards the top. Starting with a large circular base the tower gradually becomes narrower upwards to about three-quarters of its height, after which it continues the same size up to the top. In some cases the upper part has a gently swelling curve outwards to a cornice at the top, designed to throw off the waves when running up the tower and to prevent the water striking the lantern." A building constructed in this way produces a low form of gravity; great strength is therefore imparted to the lower part of the tower; it is here that the greatest strength is required, for here the greatest force of the waves is expended.

A lighthouse is so constructed that it is practically all one stone; the stones are joined by dove-tailed joints, by metal bolts at the sides and at the top and bottom. No single stone can therefore be removed without disturbing the rest. Such a mass of stone weighing, as in the latest Eddystone, 4,000 tons, is not likely to be removed by the force of any ordinary storm, especially when we remember that the tower is fixed to the rock in the same manner as it is erected, so that for all purposes the tower and the rock are one piece of stone.

Builders of lighthouses have many points for consideration. Proper means of landing must be provided; a sufficient internal space must be arranged; the building must be properly ventilated, and there must be ample accommodation for storing coal, water and provisions.

Among the eminent builders of lighthouses may be mentioned the names of Smeaton, Stevenson, Walker and Douglass. Everyone knows that on the Eddystone Rock, fourteen miles S.S.W. from Plymouth, three lighthouses have been constructed—Winstanley's wooden building, swept away in a storm, November 26, 1703; Rudyerd's lighthouse, of wood and stone, destroyed by fire, 1739; and Smeaton's, made entirely of stone. This stood from 1756 to 1882, and was only removed because the rock upon which it was constructed gave way to the violence of the waves. Sir James N. Douglass built the fourth Eddystone on a neighbouring reef in 1882. It may be interesting to compare a few particulars in connection with Smeaton's and Douglass's work. Smeaton's tower was 95 feet in height, Douglass's 170 feet. Smeaton's contained 988 tons of stone, Douglass's 4,668 tons. Smeaton's cost 40,000*l.*, Douglass's 61,500*l.*

The writer in a recent conversation with the keeper of the old Eddystone, now on Plymouth Hoe, heard the opinion expressed that the new Eddystone was too tall, the light being somewhat obscured by fogs, which would not be the case had the tower been lower.

Many interesting particulars might be given of the Bell Rock, the Skerryvore, the Wolf Rock and others, each of which has its own peculiarity, but space will not allow those peculiarities to be inserted here.

The internal arrangements differ somewhat in various towers. The water-tank in the new Eddystone is below the entrance; in the Bell Rock it is just above; in the Skerryvore it is on the same level. The room for the storage of oil generally comes next, but in the Skerryvore it is on the top, just under the lantern. The next floor is allotted to coal storage; then comes the room for provisions and above this the kitchen; higher still come the bedrooms, the living room, a library, and at the top we find the light-room and the lantern.

The central point of attraction in a lighthouse is of course the light which it is constructed to shed forth. The value of the light depends upon the use it is to the sailor, for however brilliant that light may be, or however complicated and expensive may be the means of its production, all is useless if the light will not penetrate the darkness and bring hope to the despairing mariner.

By what kind of light a lighthouse is illuminated depends very often on the position in which the lighthouse is placed. A lighthouse on a rock far from the land must necessarily be illuminated by oil. A lighthouse to be illuminated by gas must be in the neighbourhood of a gasworks, and a special gas, made from expensive cannel coal, must be provided. To be illuminated by electricity, valuable machinery must be erected, and skilled men placed in charge. Whether the lighthouse be illuminated by gas or electricity, there must be a certain amount of space available for the necessary plant to produce the illuminating power. Such space can never be found on rocks out at sea.

Nothing need be said as to the experiments with the oxy-hydrogen, the Bude and the voltaic lights; all that is necessary is to refer to the varying powers of oil, gas and electricity.

Oil carries the palm at the present day. Previous to 1846 oil obtained from the sperm whale was chiefly used; from the high cost of such oil, or what is generally known as colza oil, this is now giving place to petroleum or rock oil. It is well known that in burning either a candle or oil it is the gas or vapour given off which is really burned; the candle or lamp is therefore a small gasworks. Vapours are given off by mineral

oils at a low temperature, and when these vapours are mixed with atmospheric air, the presence of a light may cause a dangerous explosion. This explains the cause of the many accidents which occur when thoughtless persons endeavour to discover an escape of gas with a light in their hands, the gas alone being not explosive, but mixed with air is highly so. It was therefore important to take from the oil its more volatile portions, so as to reduce the flashing point; thus, with ordinary care, an oil having a flashing point above 100 deg. Fahr. is quite safe.

There are many objections to colza oil. Capillary attraction is not so active with it as with mineral oil, and it is double the price of paraffin. The rays of light produced by the burning of any gas must be caught as it were and amalgamated, so that the united rays may go forth in the required direction. In the lighthouse we have a fixed light, which must always be of the same power. This might be produced by a naked flame, but then a large quantity of the light rays not falling on the navigable track of shipping would be lost. Some rays would be too high up in the air, others would be too low down. Some arrangement is therefore required which will bend down the rays going too high, and bend upwards those pointing too low. The lamp of a lighthouse is arranged to bring about this object. Let us see how this is arranged.

1. When a ray of light passes from one medium to another of the same density, and in a perfectly straight line, no alteration of its course takes place, but if the light passes in an oblique direction its course is refracted, or bent from its natural path.

Such a bending of a ray of light is carried out when light passes through an ordinary reading or burning glass, or, as it is generally designated, a double convex lens. Suppose that AB is such a lens; a ray of light, CD, falls perpendicularly on the refracting surface, and passes straight through the glass to E. The other two rays, FG and HI, fall at an angle on the lens, undergo refraction and are bent inwards, and so meet at the point E, known as the principal focus.

In many lighthouses the system known as the catoptric, or reflective system is in vogue, oil being the illuminating agent. A number of Argand lamps are employed; behind each is a metallic reflector, shaped like a cup; the reflecting surface is very highly polished, the cistern containing the oil to feed the lamp being placed at the back of the reflector. The rays from lamps placed in such a position fall, of course, upon the sea, but many fall upon the polished surface of the reflector, and are there reflected forward.

A number of such lamps are placed on a framework; at a short distance the beams from each lamp will meet and form one large beam of powerful light, so that the mariners see only one light, and not a number of lights. Such a system requires a large number of lamps, a large consumption of oil; the reflectors require much polishing, there is much trimming and cleaning, much time is occupied, and the whole system is described as cumbrous and troublesome.

In another system, designated dioptric, or the system of lenses, we have a number of concentric rings; two to six wicks may be used, thus forming one great blaze of light, this powerful lamp being enclosed in a glass hive 2 to 6 feet in diameter for a fixed light.

The dome and lower belt of this hive catch the rays proceeding obliquely upwards or downwards from the central lamp. A careful mathematical arrangement of the prisms is necessary that the rays may be caught, and by refraction and reflection sent forth in parallel lines. The central belt gathers up the rays also and sends them forth in parallel lines; the rays from the dome and the lower belt coincide with the rays from the centre light, thus forming one powerful beam of light streaming forth from the centre of the apparatus.

A six-wick light will give a light equal to 722 sperm candles, a flame 5 inches in diameter, and will burn about 1,750 gallons of oil in a year.

For a revolving light the hive is divided into segments or panels; a separate beam is thus sent forth by every segment; the hive being made to revolve we have intervals of light and darkness; there is, therefore, a constant waxing and waning of light. When group flashes are required the panel is further subdivided; thus, one panel will in this way be made into several smaller panels, each giving a beam or flash, a short interval of darkness separating the flashes.

Sometimes 20 feet below the actual light is seen another light. This is caused by the light falling upon a hole in the

floor, and thus on to another reflector, so placed as to reflect the light through a lower window out to sea.

This method of an apparent light is carried out at times on a much grander scale. Thus, the Armish Rock, Stornoway Bay, which is separated from the island of Lewis by a channel over 500 feet in width; from this rock shines a magnificent light, and yet it is only an optical delusion, there being on the rock only a conical beacon with mirror and prisms. The explanation is simple. From a window in the lighthouse or Lewis a stream of light is sent forth; this falls upon the mirror on the rock, and thus a light is given to show the dangers of the rock.

With gas and electricity there are no reflectors. Lighthouses illuminated by gas have lamps with a number of concentric rings. Six rings of jets will have a varying number of jets of gas, the innermost having 28 jets, the outermost 108. The cost of gas is enormous; a 48-jet burner will burn 1,000 feet of gas an hour. This, in consequence of the great expense of production, will cost at least ten shillings. The cost, therefore, of a lamp burning some 340 jets of gas must be enormous.

The use of electricity in lighthouses has had a varying experience; much depends on the formation of the rock or the coast upon which the lighthouse is placed. Thus, when the electric lamp shone forth at Dungeness it was found to have many disadvantages; the use of oil was therefore resumed. At a low elevation the glare of the electric light was found to be dazzling and bewildering; the sailors could not judge accurately of the ship's distance, and, especially when a ship was approaching the shore, were unable to see the light of any intervening vessel. It may be mentioned that the Conservators will not allow the use of electric light on the bridges crossing the Thames, the shadow caused being dangerous to the river traffic.

In lighthouses the only colours used are white, red and green; the coloured lights are produced by the white light passing through coloured glasses. In doing so, the light is much weakened, white light passing through a red glass losing half its power. To those not acquainted with the system adopted it must seem bewildering to the mariner to distinguish one light from another; but since all the characteristics of each individual lighthouse are correctly stated on charts, and since lights of the same character are seldom placed within a hundred miles of each other, the difficulties are not great in clear weather, though of course greatly increased when a hazy atmosphere overhangs the sea.

Many suggestions are made to the Trinity House for the improvement of lighthouses, but most of them are found to be very futile. One suggestion was that all lighthouses in a certain district should exhibit a certain uniform colour, and that only. Thus all the lighthouses in Essex would be white, all in Suffolk blue, all in Norfolk red, and so on; but this would be practically impossible, for all colours cannot be readily distinguished at a distance. Another suggestion was that every lighthouse should be supplied with a small steam boiler, upon which a certain unseen whistle should be placed. These were to be sounded automatically by the boiler being fitted with a crank and a barrel, similar to a barrel organ; the number of sounds given forth would indicate the position of the lighthouse. One of the numerous suggestions for the protection of vessels nearing the Goodwin Sands was that small attached balloons should be placed near, they being of sufficient power to raise beacon lights to any required altitude.

The lighthouse is undoubtedly a sign of brotherly affection; its cheering beams speak of a desire to inspire hope and to save life. We may repeat the words of Longfellow:—

Sail on, it says, sail on, ye stately ships,  
And with your floating bridge the ocean span;  
Be mine to guard the light from all eclipse,  
Be yours to bring man nearer unto man.

## THE NEW MUSEUM FOR EGYPT.

THE foundation-stone of the new museum, destined to contain the national collection of Egyptian antiquities now at Gizeh, was laid on the 1st inst. by the Khedive, says the correspondent of the *Times*, the ceremony being attended by the Ministers, high officials, the Diplomatic Corps and a few invited European residents.

An Egyptian monolith coffer of the twelfth dynasty, about 2500 B.C., was used to hold a box containing the following objects:—The *procès-verbal* of the ceremony in French and Arabic; an account of the finding of the coffer; a bronze medallion portrait of the Khedive, bearing on the reverse the names Abbas Hilmi II., Khedive; Mustapha Fehmy Pasha, Prime Minister; Hussein Fakhry Pasha, Minister of Public Works and Instruction; J. de Morgan, Director-General of Antiquities; Marcel Dourgnon, architect; specimens of current coins, photographs on parchment of the plans and façade of the building, an ivory metre measure, a copy of the building speci-

fications and copies of native and European journals published in Cairo.

The ornamental design of the *procès-verbal* represented two pylons, on which, after the names of Champollion and Mariette, inscribed as the chiefs amongst Egyptologists, were those of Rosellini, Nestor l'Hôte, Lepsius, De Rougé, Brugsch, Prisse d'Avennes, Chabas, Lieblein, Maspero, Dumichen, Lepage Renouf, Grébaut, Lanzone, Naville, Schiaparelli, Erman, De Morgan, Lenormand, Pleite. The only English names inscribed on the document were those of Birch and Goodwin. The coffer, after being lowered into an underground cavity of masonry, was finally covered with a large cubical block of stone.

Comment has been excited at the exclusion of such eminent names as those of Belzoni, Young, Wilkinson, Petrie, Spiegelberg, Sayce from the roll of Egyptologists deposited under the foundation-stone of the new museum.

The building is to be completed by March 1899. When it is considered that in that time a building, roughly speaking, 125 metres square, with a mean height of some 22 metres, is to be constructed—not to mention the levelling and enclosing of the precinct—it will be seen that the Italian firm who have undertaken the contract have a heavy task before them. The credit at present voted for the undertaking is 110,000*l.*; the contractors' estimate is about 17,000*l.* less than that figure, but this balance will be none too large to cover all the extra expenses which will be incurred before the building is ready to receive the treasures of Gizeh.

The new museum is to be an improvement in all respects on the old. Its site is on the Cairene bank of the river, just below the Kasr-el-Nil bridge, and as convenient to the best quarter of the city as could be obtained where so large a plot was in question. It is within a short distance of both the river and the railway sidings, and the transport of large monuments to it will be even easier than to Gizeh. The proximity, however, of a river which periodically overflows its banks has obvious disadvantages. The architect proposes to obviate flooding by the method which (after much tribulation) has proved effective at the British Agency, namely, by surrounding the building with a wall of concrete some 2½ metres high, and the rising damp is to be combated by a very thorough system of cellar ventilation.

The new building is to be classical with no distinctively local features. The architect has exercised a wise discretion in eschewing the adaptations of the Egyptian temple style which found favour with many of his competitors. Externally the most noticeable points will be the cupola, rising some 32 metres above the pavement of the Hall of Honour, and a columned portico of severe but not unpleasing character. It is to be hoped that a judicious reserve will be maintained in the matter of its decoration. It is probable that large Egyptian monuments will be displayed between the columns, and with these nothing florid or trivial in the classical style would agree. Egyptian decorative methods, on the other hand, could not be applied to a classical building. At the two ends of the portico will be rooms opening directly into the precinct, of which it is intended that one should be the *Salle de Vente*, where duplicates and surplus objects are on offer at fixed prices to the public. This store will be open to buyers even when the main building is closed, and should prove an investment even more remunerative than at Gizeh. It is something for the tourist to know in the land of forgery *par excellence* that there is one place at least where he can purchase with some assurance of not being egregiously cheated.

As the light is almost all to be supplied from the roof, the side and rear walls of the building will be pierced only by doors and ventilators; and, indeed, the sides are to be left in the rough for the present to admit future lateral extensions.

Internally special attention has been directed to the questions of light, ventilation, and what may be called perspective. The visitor on entering will be struck by the absence of party-walls, whose place is taken by columns. By this arrangement not only will lightness and airiness be much promoted, but supervision will be exercised easily by a *personnel* far smaller than that at Gizeh at present. Although the building is to have an upper storey, all light will be obtained from the roof by the device of carrying every alternate hall right up the whole height of the building. The intermediate halls will obtain their light slantwise from their neighbours, and will thus be suited especially for the display of bas-reliefs, always most effective when illuminated obliquely.

A system of double roofing will be adopted to lessen the summer heats, and this with the elaborate ventilating apparatus ought to make the new museum one of the coolest places in Cairo. It ought to become a most popular resort, and the Department of Public Works would have no reason to regret their policy were they to lay out a public garden in the precinct. Could the strip along the Nile be included ultimately the attraction would be greatly increased. One of the most obvious needs of modern Cairo is a really pleasant garden on the right bank of the river.

The arrangement of exhibits is hardly determined on as yet. Speaking roughly, the small objects will occupy the upper floor, the famous jewelry of Dahshur being assigned an honourable place above the portico. It is to be hoped that a chronological system will be adhered to as far as possible. Even the division of small objects from large is objectionable. The magnificent collection at Gizeh, it will be seen, is in a fair way to be housed worthily. In the meantime, stimulated by the prospect, those in authority will perhaps see their way to introduce certain reforms into the department of antiquities, than which department none in Egypt stands in more need of reconstitution. Crying necessities of detail are being attended to already. A beginning has been made this season with a new and adequate catalogue of the Gizeh treasures. A German Egyptologist of distinction has made considerable progress with the description of the exhibits of the Old Empire, and so fully is the urgency of this work recognised that there is little fear that the new museum, on its completion, will be even as Gizeh has been all these years. We may look forward also with confidence to proper labelling.

Unfortunately, however, both money and men are wanting at Gizeh, and reforms, to be effective, must not be in details only, but in the general constitution of the department. The Service des Antiquités under its existing constitution dates from the days of Bulak, and is quite inadequate to the needs of the present time, when not only are the collections enormously increased, but excavations are carried out on a much larger scale, and the demand for the preservation of ancient sites and monuments, being much more imperative, requires a huge body of watchmen, overseers and the like scattered up and down the great length of Egypt. The Director of Gizeh is head of the whole under the Department of Public Works, and he has in fact three distinct functions, each sufficient for the energies of any single official. He has to direct the great museum itself, with its large *personnel*, workshops, library and so forth; he has to supervise or himself conduct excavation and exploration carried on at great distances from the museum, and lastly, he is responsible for the maintenance and proper guarding of monuments everywhere, and to that end has under his orders as mudir a very numerous irregular police.

Until the irregular police of the Service des Antiquités is put upon an equal footing with the regular guardians of the peace, so long will the penal provisions of the law regarding antiquities remain practically a dead letter in Egypt. As Professor Petrie told the subscribers to the Egypt Exploration Fund last November, convictions under that law are almost unknown; while, none the less, destruction of monuments by natives, stealing from European conductors of excavations and rifling of sites, in spite of custodians and overseers, are things of daily occurrence. Far more antiquities are found by Arab diggers in the summer months than ever are unearthed by licensed excavators in the winter. A hillside left smooth one season is found honeycombed the next; the dealers' shops are crammed with every sort of *antiqua*—and no one is one penny the worse. As soon as the inundation is on the fields the cultivators occupy their enforced idleness with tomb-opening and town-rifling, secure both of a liberal market and complete immunity. The breaking and scattering of precious things goes on unchecked, and every day evidence is lost never to be recovered.

Much good might be done by making the local sheikhs and headmen of villages responsible—something more by placing the ghaffirs (watchmen) themselves on the same sort of footing as policemen, giving them a semi-military organisation, a uniform, and European inspectors. The "Mudir of Antiquities" might still exercise supreme control, and secure their duties being performed more effectively than they might be if his police were confounded with or absorbed in the regular force. A few convictions in native courts also would do a world of good. But native judges, witnesses and police are notoriously not to be reckoned upon with any confidence, and we suspect that more would be effected in a season by a measure of a wholly different kind than in ten seasons by any that we have indicated hitherto.

The universal digging by natives is due directly to the openness of the market in antiquities. Dealers are always at hand to buy. It is useless to raid or prosecute them, even if they do not trade under consular flags. They can always hide away their treasures when danger, of which they always have warning, threatens. The raids undertaken a few years ago at Luxor proved totally futile, and have never been repeated.

The ultimate market, however, is not in Egypt but abroad. As there would be no diggers without dealers, so there would be no dealers without foreign collectors. If Egypt wishes to abolish the illicit digger and dealer she must put herself in the position of Greece or Turkey, and absolutely prohibit exportation of antiquities without exception or reserve. Such a protective measure, however, entails upon the country which passes it the obligation to preserve exhibits and publish all its treasures as well as any other country could do it. Greece, it may be said, fulfils this condition now; Turkey, needless to

say, does not. Egypt at this moment could not do all she ought. So long as her museum is at Gizeh she cannot exhibit worthily; so long as her department of antiquities is constituted as at present she lacks both men and money for proper study and publication. What, for instance, could have been done at Cairo with the papyri of Aristotle or Bacchylides?

The Government has a year or two before it. By the time the new museum is finished perhaps a reconstitution may have been effected which will make a protective law possible and justifiable. In such reconstitution there is no reason why French influence should be impaired. Science at least ought to be closed ground to international intrigue. The claim of France to be in the high places of Egyptology is based on such great achievements and services in the past that there may well be conceded to her for years to come the proud position that she occupies at present at Gizeh. But that position entails great obligations, and whoever holds it must not fall short in the competition of science in which all nations partake, or fail to pursue a policy of equality and fraternity towards all workers in the same field.

### CHELSEA HOSPITAL IN DANGER.

THE recent erection on grounds belonging to Chelsea Hospital of a score or two of lofty red-brick houses, dwarfing Wren's beautiful building and disfiguring the river-bank, should draw attention to the danger which threatens a most charming fragment of old London. In Ministerial circles, says a correspondent in the *Times*, there is a restlessness on the subject of Chelsea Hospital which bodes no good. Within the last thirty years no fewer than three departmental inquiries have been held on the subject. The removal of the pensioners from Greenwich not unnaturally led to the suggestion that a similar course should be adopted at Chelsea; and so long ago as 1870 the Secretary of State for War appointed a committee on the subject. This committee, over which Mr. Vivian presided, pronounced in favour of the retention of the hospital as "an almshouse of the best description for the most infirm and helpless of a body of about 64,000 pensioners." Such a decision might have been accepted as final, but the modern preference for out-pensions was not so easily to be set aside. In 1881, Mr. Childers referred to a second committee the question, already answered in 1870, whether the in-pension system at Chelsea should be continued. This committee confirmed the view of its predecessors, holding that a special institution for the helpless would always be needed in connection with the army, and that "Chelsea Hospital appeared to be admirably suited for the purpose." But a loophole for further inquiry was left by sundry allusions to the probable effect on the hospital of the short-service system; and accordingly, in 1894, a third committee was appointed to consider the broad question "whether the revenues of Chelsea and Kilmainham Hospitals could be more advantageously used for the benefit of the army." This committee, upon which three members of the House of Commons sat, had before them a proposal of a pensioners' association, advocating the sale of the two hospitals, and suggesting that by this and other means an additional 6*d.* a day might be provided for a large number of the oldest army pensioners. The committee examined a considerable number of the inmates of Chelsea Hospital, and took evidence as to the value of the land. The result of their inquiries was the conclusion that "the hospitals of Chelsea and Kilmainham should continue to be maintained for the benefit of deserving 'aged, maimed and infirm' pensioners."

Such decided opinions expressed by three independent tribunals of inquiry, composed of officials of high rank, of soldiers and civilians, and of members of both Houses, might be thought to have placed Chelsea Hospital beyond danger. Unfortunately, we have the very practical comment embodied in the glaring bricks of "Embankment Gardens"; we have the fact that his Royal Highness the late Commander-in-Chief, who was a staunch upholder of Chelsea, has ceased to hold that high position; and we have a suggestion of the last committee of inquiry which is, perhaps, almost as dangerous in its way as the proposal to abolish the hospital in favour of out-pensions. The committee advise yet a further inquiry "as to the necessity for an increase, either at present or in the near future, in the accommodation of Chelsea Hospital"; and they further recommend that "the question whether any portion of the lands of the hospital could be disposed of to provide a fund for such purposes without detriment to the hospital should be included in such an inquiry." Indeed, it was proposed to the committee to sweep away the present hospital and to build a larger institution of the same kind in the country. A similar proposal recently deprived London of Lady Dacre's Almshouses at Westminster; and though, in the case of Chelsea, the committee "were not prepared to recommend such a scheme for adoption," the fact that it should have been made shows how many and various are the dangers which threaten the spot consecrated by Wren's genius. Conversion into out-pensions may for the present be

put out of consideration; but demolition for the purpose of reconstruction elsewhere, or enlargement at the cost of a portion of its charming surroundings, are obviously still questions exercising the minds of those in authority over our military establishment.

Chelsea Hospital is of about the same age as the standing army of the country. It had its origin in Letters Patent of December 22, 1681, declaring the royal intention "to erect an hospital for the relief of such land soldiers as are old, lame or infirm in the service of the Crown, and to endow it with a revenue suitable thereunto," and constituting the paymaster of the forces for the time being the receiver-general and treasurer of "all such moneys as should be given or paid" towards the erection of the hospital. Money was not very plentiful in the days of the Merry Monarch, and the royal mind seems to have been in some doubt respecting the sources of the proposed endowment. A start was made with secret-service money and private donations, and then, fortunately, more permanent means were found of defraying the necessary expenses without increasing the cost of the army. Sir Stephen Fox, when paymaster of the forces, hit upon the brilliant idea of at once serving his own interests and those of the soldiers by making prompt payments of the sums voted for the army at a discount of a shilling in the pound. This discount he afterwards surrendered to the Crown, and one-third of it was allotted for the expenses of his office, and another third to Chelsea Hospital. The allotment to Chelsea was made in 1683, and in the following year the revenues of the hospital were further increased by the deduction every year of one day's pay throughout the army. With the moneys thus provided over 60 acres of land were purchased at a cost of about 1,000*l.* an acre, and a building capable of receiving nearly 700 inmates was built at a cost of 145,000*l.* It would be out of place to dwell upon Wren's work. Constructed of the simplest materials, brown and red bricks and grey slates, the hospital has that freedom and nobility of line, combined with delicacy of finish, so rarely to be met with in buildings of the present day. Facing towards the river, it stands on a succession of broad, low terraces, while on all sides wide walks and spacious lawns were designed by the architect to harmonise with the central structure, and to carry on the prevailing idea of size and repose. The building itself remains substantially as it issued from Wren's hands, but in its surroundings changes have taken place. Originally canals, after the fashion so dear to the French school of gardening, ran below the terraces of the hospital and on either side of the broad walk to the river, to which access was given by a handsome flight of stairs. The canals have disappeared, and an unmeaning row of bushes has been planted at the foot of the terraces, while the Chelsea Embankment has—very unnecessarily, one would think—abolished Wren's stairs. Landward, the hospital looked upon a noble garden, almost as spacious as that on the river side, and this in turn was approached from the King's Road by a long double avenue. Garden and avenue still remain, but the garden has been severed from the building, to which it gave dignity and importance, by a modern road which passes almost under the windows of the hospital. Thus detached the garden has been laid out as a cricket-ground, and now goes by the name of Burton's Court. On each side of the avenue small houses, in no way in keeping with such an approach, have been built, and the treatment of Burton's Court, as well as the interpolation of the new road, has obscured the meaning of the original plan. There have been some filchings also for building purposes, notably an acre and a half leased for industrial dwellings about twenty years ago. Nevertheless, until the recent erection of the new houses on the river frontage no very serious injury had been done. The simple but beautiful lines of the hospital could still be seen from all sides; and its rich, sober colouring, in contrast only with the grass and trees of its grounds, was still saved from the intrusion of any jarring element. This can no longer be said. From Battersea Suspension Bridge the new houses obstruct the view of the hospital; and from the Battersea bank they are painfully conspicuous—inharmonious in height, in colour, and in the evidence they obtrude of painful effort to house large numbers on a small plot of land—an object so foreign to the amplitude of Wren's design. An ugly blot has been made upon a beautiful picture—a picture of the greater value to London, because she possesses so few of them. It is for the public to see that this blot is not followed by others, until the picture is blurred beyond recognition.

Such places as Chelsea Hospital, indeed, sorely tempt that desire to make money for money's sake which constitutes a weak side in the English character. Here is a large area or land, used merely as the garden of an old-fashioned mansion, and as an open space upon which a few old soldiers may breathe fresh air, sun themselves in summer and see something of their neighbours. It is true that the garden is open to the public and is incidentally of great value to the crowded districts of Chelsea. Still, it might be sold for building by the square foot. There are persons who have a feeling that it

is almost sinful to waste such an opportunity, although they may value the place in itself and may have no very distinct views as to the use to be made of the money produced by a sale. The rent of the land now occupied by new houses—750*l.* a year—has been applied, we are told, in giving extra comforts to the pensioners of the hospital. Everyone would wish that the invalid veterans should have all possible comforts; but, seeing that Chelsea Hospital is now supported mainly by Parliamentary votes, it would surely have been better to add the paltry sum required to the amount voted by Parliament rather than to disfigure the hospital grounds. It is pleasant indeed to note that there is some growth of opinion on these subjects. The committee of 1894, in discussing the proposal to demolish the hospital, question whether "the public, the London County Council, or Parliament" would look with equanimity upon the covering of the ground with streets and houses after the sweet will of the speculative builder. The danger is that steps to this end may be taken without the full knowledge of the public. The hospital estate is administered by a board of trustees or commissioners appointed by the Crown, and composed mainly of military and civil representatives of the War Office; and these commissioners have been advised that they have power to let the hospital lands on building leases. In the exercise of this power the charm of the hospital has already been marred; further leases for the purpose, for example, of enlarging the hospital, may produce yet worse effects. It should not be in the power of any commission to injure a national possession of the great value of Chelsea Hospital and to deprive its inmates and the public of London of a priceless open space without the authority of Parliament, given after full discussion. Whatever the interests of the army may from time to time demand—and upon this question opinions have differed in the past and are likely to differ in the future—it is abundantly clear that in the interests of the capital and of the nation a beautiful specimen of the genius of the most characteristic English architect should be left intact in the midst of the harmonious surroundings which alone enable the graceful simplicity of the design of a master-mind to be appreciated. When the New Forest was threatened with destruction at the hands of a Government department, Mr. Fawcett obtained a pledge that no further action should be taken without the sanction of Parliament. A similar undertaking should be obtained—and that without delay—in relation to Chelsea Hospital.

The following letter appeared in the *Times* on Thursday:—  
Sir,—As a lover of old buildings and open spaces, I find myself in complete sympathy with your article of to-day under the above heading.

But, as the architect of the houses and flats which form the text of the article, and upon which you vent your wrath, I feel that your note of warning would have been equally effective without the incidental attack upon the design of my work.

It is an ineffective form of criticism that would compare the old and the new in architecture. It is unjust to the new, and a slight upon the old; and the argument that the amenities of Wren's structure should not be disturbed is not helped by taunts thrown at modern work, produced under such different conditions and for such different purposes.

If my buildings dwarf Wren's structure they do not necessarily "disfigure the river bank," any more than other groups of buildings, by more eminent hands, which line the remainder of the embankment.

All red bricks are "glaring" until the weather has toned them; and the unconscious charm of the hospital itself is largely due to the mellowing influences of the atmosphere.

Although the land I have covered is part of the estate of Chelsea Hospital, it was not part of the familiar grounds which still surround it. As a matter of fact it was a triangle of ground detached from the hospital gardens, and formerly part of the grounds of Gordon House, at one time the residence of General Gordon.

The land itself was more or less waste land, and had been the scene of the Naval Exhibition of 1891 and of the Military Exhibition preceding it.

With due regard to a profitable development of the land, I have made every endeavour to preserve the amenities of the neighbourhood, in illustration of which I may state that, of the total area of about two acres, only about five-sixths of an acre is occupied by the houses known as Embankment Gardens and by the flats known as Chelsea Court, the remaining one and one-sixth acre being devoted to spacious roads and ample gardens, thus completely answering the suggestion in your article that the development is evidence of "painful effort to house large numbers on a small plot of land."

The encroachment now being an established fact, it may not be out of place to consider its economic advantages to the institution.

A ground-rent of 750*l.* a year has been established in favour of the institution, with a reversion at the end of eighty years to buildings that have cost something under 150,000*l.* to erect—

more than the cost of the building of the hospital itself, as stated by you.

This ground-rent could be sold, no doubt, at thirty years' purchase, producing a capital return of 22,500*l.* for the two acres, which represents 11,250*l.* an acre, and which compares favourably with the 1,000*l.* an acre paid for the land in 1683. This operation would thus produce a sum of money which could be usefully applied for the enlargement of the present hospital.

As a detail of secondary interest, I may point out that the execution of my designs for the houses and flats has given employment to many hundreds of artisans in all trades over a period of more than two years.

Personally, I am accustomed to these outcries as soon as the new impinges upon the old; for example, when, some years ago, I pulled down St. Paul's Schools in St. Paul's Churchyard and built thereon huge stone warehouses, an agitation was started for throwing this priceless land into the public way in order to improve the view of St. Paul's Cathedral.

However much one's pulse may be stirred by the nobler monuments of the unapproachable Wren, and however much one may hunger to preserve all possible open spaces in this overcrowded city, it will be found impossible to resist the natural tendency in the development of a huge metropolis towards the new encroaching upon and obscuring the old.—  
Yours obediently,

DELISSA JOSEPH, F.R.I.B.A.

17 and 18 Basinghall Street, E.C.: April 21.

### A NEW GUILDHALL FOR LONDON.

A PAPER was read last week before the members of the Bishopsgate Ward Club, by Mr. Alfred Frampton, on the question of a new Guildhall for the City. The following report of it appears in the *City Press*.

Mr. Frampton said:—The first publication of my views on this subject appeared in the columns of the *City Press* some three years ago, when the London County Council possessed far greater public esteem and more Parliamentary power than now. The members of the Corporation were then dreading that the coming mayoralty of Sir Joseph Renals, Bart., would be the last scene of all that would end this strange eventful history of the most ancient and privileged City of London; but happily the City is not at present threatened by its former rival, the London County Council, as that body has lately been too much occupied studying the curious principles of betterment and investigating its own intricate affairs, which are evidently too much for it to manage without worsement creeping into its unwieldy organisation. To-day the City is enjoying a most undisturbed and honourable truce, luxuriating beneath the shades of its once powerful rival, and basking in the sunshine of the Diamond Jubilee year. The City is, therefore, enabled at the present time to pursue the arts of peace and progress without fear of being incorporated into a mushroom organisation not yet in its teens; and, further, a great change is taking place in the destinies of outer London, many a district considering the desirability of managing its own local affairs. In this direction Westminster, Kensington and Marylebone are leading the way to a new order of things that will encourage more men of position and learning to identify themselves with municipal affairs. Provincial cities and towns such as Manchester, Sheffield, Portsmouth and many others, have with much public spirit erected municipal buildings in accordance with their requirements and worthy of their proper dignity. Unfortunately the City of London cannot do likewise, as it is at present suffering from two great disabilities. Firstly, the Common Council of the City of London is not, as elsewhere, a power and the stepping-stone to the civic chair, the dignity being entirely monopolised by a few apathetic lifehold aldermen, who almost invariably have their equals, and often their superiors, in their own wards amongst the representatives of the Council. This is a system which dates from 1475, prior to which time the whole of the citizens elected the mayor and sheriffs; that ought to be so again, and if that cannot be accomplished forthwith then the best and most capable alderman should be selected to fill the civic chair, for seniority is an absurd theory when capability is the requisite. This year the City is most ably represented by Mr. Alderman Faudel Phillips. Why the Common Council in these days of strikes have never thought of taking a holiday is really astonishing, but sincerely must we pray that this change will soon take place, and a greater public spirit be infused into the Court of Common Council, which certainly would take place if all the members of the Court were eligible to fill the highest office in the City. The London County Council is the City's second disability as regards power, and until the County Council is abolished and outer London subdivided into municipalities, the City of London, aye, and even London itself, will ever be in an anomalous position. The City at present arrogates to itself the representation of London, but it is only a

square mile of it, with one-eighth of its rateable value. The City should therefore endeavour to reform itself whilst its friends hold political power, and the achievement of its requirements is still attainable, or unification may incorporate the City, and a new Guildhall worthy of all London may be located in some place not at present dreamt of. Manchester, Leeds, Sheffield and Portsmouth all have fine municipal buildings. London, however, is unable to possess a building worthy of its position, it being too poor and unable to afford it, or else too indifferent; but let us hope that ere long the municipality of London may become as rich as some of the provincial cities, and be willing to uphold the dignity of the Metropolis. I do not intend to give a long historical account of the present Guildhall buildings, for the Great Fire almost swept away the original Mediæval structure erected in the reign of Henry IV., leaving only the piers and crypt of the large hall as mere relics of the glories of two centuries and a half. Since 1666, that memorable year in the history of the City, another two centuries and a half have almost rolled away, and to-day these fragments of 1411 are still being solemnly surrounded by all the architectural incongruities of construction that the ingenuity of man can devise. The large hall, which is built on the original lines, is exceedingly well proportioned and beautiful, but the roof and many of the embellishments belong to the present reign. The civic buildings surrounding the hall are fine examples of architecture, but the relative positions they occupy to the large hall are most aggravating, and it really seems as if the object of every alteration and addition were to put the main floor of the new building on a different level from any other. Why this principle should have been adopted is a profound secret. Were a live turtle let loose in the large hall, or in any of the chief apartments, he would certainly be unable to extend his knowledge of the surrounding buildings without elevators being constructed at numerous points for his special convenience of going up or down stairs. The new buildings for the Commissioners of Sewers have gone down steps costing something like 10,000*l.*, and what the level of the ground-floor will be it would be interesting to learn. The Corporation has lavished its treasures most unwisely, and produced a tangle and jumble of buildings that are a standing disgrace to the first city of the world. Some may reverently refer to the old associations of this centre of municipal authority, and cherish the spot where the great of this nation and of other lands have met, and by their presence recognised the power of municipal institutions which has been much to their benefit and to the City's great praise. Mr. Frampton next showed that the population of the City was 31,148, and the rateable value 4,481,860*l.*, the population of the county being 4,433,018, and the rateable value 31,351,608*l.*, while London had a population of 4,464,166 and a rateable value of 35,333,468*l.* Liverpool's population, he pointed out, was only 629,443 and the rateable value 3,775,045*l.*; Manchester came next with a population of 529,561 and a rateable value of 2,934,545*l.*

Continuing, Mr. Frampton said:—The present is a desirable period for the citizens of London to compare its administration and municipal buildings with those of other corporations, in order to consider how it stands relatively with them, and also to consider whether it is or is not behind the times. Certainly during the present reign it has stood still and merely occupied the proud position of being the municipality of part of the Metropolis dispensing hospitality for the whole. The administration of London as it now exists is a miserable muddle, and is by no means a model municipality for our provincial and colonial cities to copy. The City has opposed its own development and progress in the past, and the inclusion of Southwark will hardly save its position in the future. The Board of Works has come and gone, the County Council has come, like its predecessor, but is not yet in its teens, and is infinitely less popular than the City administration and has probably not come to stay. It therefore behoves the City of London to begin making arrangements for possessing majestic municipal buildings within the City area worthy, not only of the City, but of the Metropolis. The Christ's Hospital site might be purchased, and possibly no other large site will ever come into the market in consequence of all the open spaces in the City being covered. The Mansion House should be sold, the money obtained being applied to the purchase of the Christ's Hospital site, and the present Guildhall should be converted into a Mansion House with museum, library and picture gallery attached. The scheme would cost about a million and a half, or about the amount that Manchester expended when its rateable value was about half that of the City of London, and its population about 350,000. Finally, the City should look ahead and prepare for developing its power and position, and, above all, it should prevent any other local body or union of local bodies from usurping its position as the centre of the administrative power of London. The London County Council municipal offices are not yet erected at Trafalgar Square. London is waiting for the City to take the lead, and to do this a municipal meeting house should be erected worthy of London, worthy of the Metropolis, worthy of the City that rules the

waves and worthy of the greatest and richest centre the world has ever seen.

In conclusion, Mr. Frampton spoke of the town halls of Belgium, and gave details of their architectural features.

A lengthy discussion followed, and a hearty vote of thanks to Mr. Frampton brought the meeting to a close.

## MODERN ART.

AT the opening of the annual exhibition of pictures (this year there are eighty-seven works by Mr. Watts, R.A.) in St. Jude's Schools, Commercial Street, Whitechapel, Lord Crewe delivered an address. His lordship said that in looking round those walls what must strike everybody above all was that they were looking at the work not only of a great painter but of a great poet. What was it that made a man a poet? Matthew Arnold had said more than once that the essence of a great poet was the application of ideas to life, and he went on to say that he was a great poet who applied to whatever subject he had in hand those ideas of nature and the life of men which he had himself acquired. That, it seemed to him, was what Watts had done in the work they saw before them. It was the fact that Watts had put so much poetry into his work which enabled him to stand the test, which was a very severe one, of having so much of his work exhibited at the same time. He ventured to think there was no artist in our time, and very few of the great masters of any time, who would stand so well as did Watts the test of having so large a number of his works hung together. The present exhibition consisted of three separate divisions. In the first place there were the portraits. A great many of the portraits executed by Watts were not there, because, with a generosity and public spirit to which he could think of no parallel, the artist had presented many to the National Portrait Gallery. They were, however, enabled to see many of great artists, statesmen and men of letters, and throughout them all there was noticeable the one special quality that they were far removed from what he might call the "coat and trousers" view of humanity, and gave a picture, not only of the outward resemblance of the men, but something of their character. Then there were the subject pictures, dealing with a great variety of matters, but whether they were taken from the beautiful old Classical myths or Mediæval stories, or from Dante, Shakespeare, or Spenser, they were all alike in this—that they dealt with the deepest feelings and passions of humanity. And then lastly, and perhaps most interesting of all, were those allegorical pictures which had made Watts's name so famous. These philosophical pictures were, after all, simple enough. They dealt with the really great things of life—faith, hope and love, and the relations between life and death; and he ventured to think that there was nobody who looked round the pictures who would not be reminded of something that had happened in the past, some hopes, ambitions, disappointments or bereavements. It was just that quality in the pictures which defined the kind of pleasure felt from visiting such exhibitions. But in speaking of some of the lessons which could be drawn from those splendid pictures they must not forget that besides conveying lessons they were also very beautiful in themselves. It was impossible to over-estimate the advantage which everyone derived from the mere regarding of something beautiful. We were all in different ways made more human by looking at beautiful pictures. We were supposed to be living in what was called a very artistic age. We drank out of art mugs; we made up our fires out of art coal-scuttles. There was a great deal of art about and a great deal of luxury, and though the so-called art might sometimes seem to be a little absurd and extravagant, it certainly had its good side if it taught people in all ranks of life to avoid what was ugly. There was also in this great spread of artistic spirit, sometimes ill-directed, but often well-directed, the further advantage that it had so affected the industries of the country that during the last twenty or thirty years there had been a vast impetus given to work in all kinds of design. The effect of that upon the workers could not be other than a good one. It must be a good thing to give workers, as was now the case, an increased personal interest in their work, and it could not be denied that, since so much impetus had been given to design a far greater scope had arisen for the exercise of personal and individual talent in the working classes. He wished the scheme for providing a permanent art gallery for Whitechapel every success.

**The Annual General Meeting** of the Liverpool Architectural Society will be held at the Law Library, Union Court, on Monday, May 3, at six o'clock P.M., and the prize drawings of the Royal Institute of British Architects, 1896, and students' testimonies of study will be on view at the same place during the week commencing Monday, April 26, 1897.

## GLASGOW ARCHÆOLOGICAL SOCIETY.

THE last meeting for the session of this Society was held in the Philosophical Institution, Bath Street, on the 15th inst., Dr. David Murray presiding. Mr. John Orr exhibited the upper stone of a quern found near Glasgow Green, and perforated stones found in the Clyde near Rutherglen Bridge. The exhibits were described by the chairman: Mr. F. R. Newberry exhibited a lease of the lands of Dryslwyn, Carmarthenshire, 1593, by T. Etherington Cooke. Mr. Macgregor Chalmers read a paper on the "Vaulting of the Lower Church of Glasgow Cathedral," in which he subjected the theory promulgated recently by Mr. T. L. Watson to a searching criticism. A careful examination of the building showed that there was no evidence that there had been any intention to carry out any design other than that existing in the centre aisle. It was found that mouldings which were described as late insertions and of late date were actually wrought on the same stone as mouldings described as of early workmanship, and it was found that the early thirteenth-century walls were designed to carry vaulting ribs which were now claimed as afterthoughts of 200 years later. The new plan proposed and described as the plan originally designed was very commonplace, and was quite unworthy of the great artist to whom they owed their cathedral. The fact that this structure was a church and not a crypt had been overlooked, as well as the significant character of the shrine of St. Mungo. The evidence of the building left no room for doubt that, whilst some part of the work betrayed want of skill, the present design was as originally projected. Professor Ferguson exhibited some English receipt books of the sixteenth and seventeenth centuries.

## SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

THE annual general meeting of the above Society was held on the 13th inst. in the library at the School of Art, Mr. Charles Hadfield, the president, in the chair. There was a good attendance of members, amongst whom were Messrs. R. W. Fowler (vice-president), Fred. Fowler (hon. treasurer), C. J. Innocent (hon. secretary), E. M. Gibbs, Joseph Smith, Thos. Winder, W. J. Hale, C. B. Flockton, C. M. E. Hadfield, J. B. Mitchell-Withers, C. F. Innocent and E. Winder, jun.

Mr. C. J. Innocent (hon. secretary) read the annual report of the council.

The statement of accounts was read, and showed a balance in hand of 43*l.* 7*s.* 6*d.* This statement and the annual report were unanimously adopted.

Mr. Mitchell-Withers and Mr. E. Winder, jun., were then elected scrutineers for the election of officers, which resulted in the following elections:—President, Mr. R. W. Fowler; vice-president, Mr. Joseph Smith; treasurer, Mr. F. Fowler; honorary secretary, Mr. C. J. Innocent; council, Messrs. A. Smith Denton, H. W. Lockwood, W. F. Hemsoll, T. Winder and W. C. Fenton.

A hearty vote of thanks was passed to the retiring officers for their services during the past year.

## THE PREVENTION OF FIRES DUE TO LEAKAGE OF ELECTRICITY.\*

(Concluded from last week.)

## Reasons for Advocating Insulating Tubing.

THE wiring system thus advocated as best and safest would be a series of continuous tubes or conduits of insulating material which can be placed throughout a building after the manner of gas or water pipes, the conducting wires being afterwards drawn into the tubes. In this way the conductors are insulated electrically from all the materials used in the building, whether plaster, wood or stone work, gas or water pipes, &c., and the woodwork of the building is effectually protected from being ignited by "leakage" or the "accidental heating" or "short circuiting" of the wires themselves. The effects of "careless handling" or "defective workmanship" are also readily detected and remedied. For these reasons the building is effectually protected from the liability of fire arising through electrical service. Insulating tubes can be found which are waterproof, and will provide a high and durable insulation unattainable by any other method or at as low cost. Such a system can be installed coincident with building construction, and lends itself effectively to the placement, alteration, repair or enlargement of the conductors. A suitable metallic armouring provides protection from external trouble, whilst all internal troubles arising from moisture or damaged insulating material on the conductors are, from a fire-risk point of view, absolutely counteracted. From a prac-

tical point of view every desiderata is provided. Any defect in the tube construction itself would prevent the wires from being drawn in, so that the raceways themselves have to be mechanically perfect. The wires need not be brought into the building until all construction work is done, and are, therefore, not so liable to accidental damage, so that increased surety of insulation on the wire itself is obtained.

A perfect insulating tube should not be liable to decomposition by heat, should withstand moisture and resist electrolysis, be cheap, durable, pliable, strong, and not liable to shrink or warp. Such tubes can be produced, and are already commercially successful.

Many independent tests have been made by well known consulting engineers and others in respect to the realisation of the above advantages. In order to reproduce the condition where the insulation between two wires in the same tube might break down, "arcs" have been formed in a tube, with the result that the arc was found to last only a few seconds and affect the tube but slightly. To reproduce the condition where a conductor becomes heated through an excessive current, an insulated wire was placed in a tube and an increasing current passed through it until the conductor was burned out. The tube became heated but was not set on fire. To reproduce the worst possible moisture conditions an armoured tube was used, slightly bent and filled with water. After twenty-four hours' soaking, an insulation resistance measurement was obtained of eleven megohms, which was maintained as a permanent value throughout the series of tests, which were continued for several days. To prove the feature of "accessibility" a wire was placed in a tube, both were kept at a temperature of 190 degrees Fahr. for fifty hours and then allowed to cool. It was then shown that there was no sticking, and the wire could be withdrawn with ease.

Turning once more to the United States fire records, one single fire will be found recorded as having occurred upon wiring carried out in insulating tubes, whilst it is a fact that there are already many more lights installed in this manner than for the total lighting of England. The report of this fire, in detail, shows that an "unarmoured" tube had been installed, and that this had been broken between floor and ceiling, probably through careless construction work; moisture was thus able to affect the insulation on the wires at the unprotected point, and a "short circuit" resulted.

In order to determine the merit of iron pipe with an insulating lining over plain iron pipe, the following tests have been made:—A length of bare iron pipe and another of insulating tubing were taken, and two insulated wires run through both under exactly the same conditions. These wires were short circuited, with the result that a hole was blown in the iron pipe, whilst the insulated iron pipe stood the test perfectly. A 150-ampere fuse was arranged in the circuit employed for this experiment.

Again, an ordinary insulated wire was taken and the insulation on it damaged; the wire was then run through both tubes, and in order to reproduce the conditions of moisture occurring, cotton waste, impregnated with a caustic soda solution, was applied to the damaged insulation inside the tube in both cases, the tubes resting on damp woodwork, side by side, about 4 inches apart. Between the tubes an iron bar was placed forming the earthed pole of a supply system. This arrangement was intended to reproduce the state of affairs that might obtain when the pipes were fastened to a floor board or wooden beam attached to the iron girders of a building.

Current was applied, and under the above conditions the "leakage" arising from the defective wire placed in the bare iron pipe caused a fire to break out on the woodwork, whilst the insulated iron tube stood the test without suffering or causing any damage. It was further found that a fire could be caused with such a small "leakage current" as 1½ amperes, a three-light fuse placed in the circuit remaining intact.

## Conclusion.

Perfect electric wiring should combine in the fullest degree the attributes of safety, accessibility, convenience, economy and durability. The author has endeavoured to point out that an insulating tube method of wiring does provide "safety" by giving the greatest surety of action and freedom from the danger of fire. In respect to "accessibility," it provides for examination, replacement or repair to any part of the circuit with a minimum of trouble and expense. With respect to "convenience," the insulating tube is first fixed, due regard being given to the requirements of the building, and then completely fulfils its function of protecting the conductors. In regard to "economy," material utilised in the highest degree must admittedly be economical. Finally, as to "durability," a tube can be constructed, the materials of which are in themselves practically imperishable, and which at the same time find preservation for the conductors.

In short, it is thought that an insulating-tube system fully meets the various conditions of safe and perfect wiring, compensating crass ignorance, and counteracting gross carelessness on the part of those installing or using the electrical service.

\* The Fothergill Prize Essay, by Mr. Frederick Bathurst, A.I.E.E., published in the Society of Arts Journal.

The true principle which should guide the insurance interests is really the absolute prevention of fire, inasmuch as any fire loss at all necessitates that the community at large suffers, the rates charged being regulated from the total actual loss of the combined companies. The continued extension in the employment of electricity for power, light and heat must, if properly directed, tend to minimise the occurrence of any fires, and it is hoped that a case has been made out to show that an insulating tube or conduit system of wiring provides the best means of preventing fires arising from the leakage of current to earth, and the other causes of danger in electrical installation.

The chairman, Mr. W. H. Preece, C.B., said he could not help calling in question to some extent the statement that moisture was so deleterious to the insulation of wires. In the branch of the public service with which he was connected, they were only anxious that the cables which ran all over the world should remain in peace and comfort at the bottom of the sea. If one thing more than another conduced to the durability of gutta-percha and indiarubber, it was its being kept constantly at one uniform temperature under water. The great evil was not moisture, but alternations of moisture and dryness, and heat and cold. Such changes caused the elasticity and viscosity of the insulating materials to disappear; then it cracked and the moisture got in, and they got electrolysis and leakage. To guard against these evils, fuses were introduced, and though he should be sorry to say one word against their proper use, he could not speak too strongly against their abuse. His experience was that out of one hundred faults in an electric-light installation, ninety-nine were due to the fuses. By the rules of the insurance companies they were forced to introduce these fuses wherever they could be put. Fortunately, he was in a position where they were not subject to these rules. The Government offices were their own insurers, and made their own rules, and they reduced the number of fuses to the smallest possible limit. It was to a certain extent a satisfaction to an English engineer, that for statistics about fires caused by electricity he had to go to America, where very interesting and valuable reports were written upon them. That was because they had so many fires, but this arose rather from climatic conditions than from difference in practice. Here there was abundance of moisture; in America it was just the reverse, for there all wood-work was in such an inflammable condition that the least spark would set it off. But there was one thing in which our practice in England differed; that was the care bestowed, first in specifying what was wanted; secondly, in having the work done thoroughly, and properly inspected; and thirdly, in being guided by the regulations of the insurance offices as well as by those of the Institution of Electrical Engineers. So long as this was done there need be little fear of danger from fire.

#### The R.I.B.A. Elections.

SIR,—The list of members officially nominated to serve upon the Council and standing committees has just been issued. There are on the four committees sixty-four positions to be filled up, and for these no less than sixty existing committee-men are self-renominated; this is unfair to those who may wish to take their turn, and contrary to the best interests of the Institute.

There is, unfortunately, a tendency causing members of the Institute to vote for those candidates who have asterisks before their names in the balloting lists (these indicating existing members); still more unfortunately, not one-fourth of the members trouble to vote at all, probably on account of those repeated self-renominations which tend to keep out of office a reasonably fair proportion of new men and fresh ideas. Surely it should be compulsory that a few each year should *not* be eligible for re-election, that others may have a chance.

With regard to the Council, matters are even worse; the president, vice-presidents, secretary and members of Council number twenty-four persons, and no less than twenty-three of these gentlemen have (officially) renominated themselves for election; therefore, having in view the manifest advantages of the asterisk prefixed, there is but small prospect that new names will appear in the new Council.

If all the members throughout the country would vote, the result of the elections might bring in new men who would restore the Institute to its former condition of prosperity. Although the income of the Institute is vastly greater than when I joined it more than twenty years ago, yet its publications are not now to be compared with those given in years past. We used to have a large and handsome volume yearly,

beautifully illustrated; but this was discontinued for the sake of economy, and now we have merely a fortnightly journal, with a higher price marked on the outside cover than the contents usually warrant.—Yours faithfully,

METROPOLITAN FELLOW.

London: April 17, 1897.

#### GENERAL.

**The Fanmakers' Company's Exhibition** will be opened on May 25 at Drapers' Hall. There will be a historical section. Several prizes will be offered for painted fan-leaves and fan-sticks.

**The Dean of Winchester** says the nave roof of the cathedral is now finished, but 6,000*l.* more are required for the repair of the other roofs, more especially of the choir and north transept. The organ is also being reconstructed at a cost of 1,000*l.*

**M. Paul Blondel**, the French architect, has passed away in his fiftieth year. About two years ago he was appointed successor to M. Hardy as architect in charge of the Louvre and the surviving part of the Tuileries.

**Mr. W. J. Locke, B.A.**, has been selected as secretary of the Royal Institute of British Architects out of fifty-seven candidates. The Council have appointed Mr. Herbert G. Tayler as assistant secretary.

**The Late Mr. G. C. Schwabe**, whose personal estate is valued at 172,472*l.*, has bequeathed 1,000*l.* to the Artists' Benevolent Institution on the death of his wife.

**A Statue** of the late Paul Baudry, the French painter, several of whose works were illustrated in *The Architect*, was unveiled by President Faure at La Roche-sur-Yon on Tuesday.

**Dean Farrar** proposes to erect a new altar-rail in Canterbury Cathedral at a cost of about 2,500*l.* Representations of the implements of the Passion, the crown of thorns, the spear, &c., will be introduced, and also enamelled shields of all the Episcopate sees of the Empire.

**The Rev. W. F. Greeny, F.S.A.**, who brought out in 1884 a collection of rubbings of monumental brasses in continental churches and one of incised slabs in 1891, died on Sunday in his seventy-second year.

**Baroness Hirsch** has given 1,000*l.* towards the erection of a nursing home in connection with Guy's Hospital.

**A Monument** of wood has just been erected over the grave in which the casket containing the ashes of Mr. George Du Maurier was deposited in the Hampstead Churchyard after the cremation of his body at Woking. The corners of the structure at the head and foot of the grave are carved uprights in the form of ancient Celtic crosses. From the uprights runs a centrepiece, on which appears an inscription giving Du Maurier's name, date of birth and death, and the following words from "Trilby":—"A little trust that when we die we reap our sowing and so good-bye."

**The Sanitary Institute** have accepted an invitation from the Council of the city of Leeds to hold their autumn congress and exhibition in that city in September next.

**An Excursion Meeting** of the Northern Architectural Association will be held on Saturday next at Messrs. Wm. Harriman & Co.'s works at Blaydon. During the afternoon Mr. W. H. Allen will kindly read a paper on "Fireclay Manufactures."

**The New Musée** in the Invalides, Paris, will be inaugurated on May 1. It will be devoted to memorials of French warriors.

**M. Aimé Morot** is engaged on a large picture representing the Emperor and Empress of Russia after passing through the Arc de Triomphe on their entrance to Paris. It is to be placed in one of the galleries at Versailles.

**Dr. Rowand Anderson** explained the principles of construction of the M'Ewan Hall, Edinburgh, to the members of the Royal Scottish Society of Arts on Tuesday last.

**The Committee** of the American School of Classical Studies in Rome offer three fellowships for the year 1897-98, of the value of 600 dols., 600 dols. and 500 dols. The holders will have to work under the director for a period of ten months.

**The Ground** in Whitehall forming part of the site of Carington House has been let by the Department of Woods and Forests for the erection of a pavilion which will accommodate about 5,000 people on June 22. The rent is 6,500*l.* and the erection will cost about 5,000*l.*

**Dr. J. W. L. Glaisher, F.R.S.**, will read a paper on "Delft Ware" before the applied art section of the Society of Arts on Tuesday next.

# The Architect.

## THE WEEK.

A COURSE of four lectures on "Design in Lettering" will be delivered by Mr. LEWIS F. DAY, at the Society of Arts, on Monday evenings May 3, 10, 17, 24, in which the following points will be discussed:—Lecture I.—*The Alphabet*.—The alphabet as we know it—How it came about—The development and growth of its letters, from the beginning to the time when the printing press more or less fixed their form—The changes through which the shapes of the letters successively passed—The mark left upon them by history—The accidental character of the letters of the alphabet—What is essential in their form, and what, for practical or artistic reasons, may be susceptible of modification and improvement. Lecture II.—*Decorative Lettering*.—The alphabet regarded more especially from the point of view of design—Its inherently decorative character—How far it was eventually affected, and to what degree shaped, by considerations of beauty—The art of the calligrapher, his influence for good and evil—The relation of lettering to the implement, *i.e.* the point, the chisel, the brush, the pen, &c., with which it is written—Penmanship *versus* printing—What decorative lettering should be, and what it should not be. Lecture III.—*Ornamental Lettering*.—The alphabet turned to deliberately ornamental purpose—How far that has been done, and how far successfully—Initial letters, as found in illuminated MSS., in early printed books, and in the books of to-day—The latitude allowed to the artist in the design of initial letters and the like, and where he oversteps the bounds—Use before beauty—Ornament overdone—Legibility in lettering imperative—The exceptional cases in which the writer may mystify the reader—What we may do with the alphabet. Lecture IV.—*Lettering in Ornament*.—The place of lettering in the general scheme of decorative design—Its introduction inevitable—The universal use that was made of inscriptions, &c., in every form of decorative art, in all countries and in all but recent times—The loss thereby to ornament—The masterly use of inscriptions in Gothic and other design—The most beautiful use of them in Oriental decoration—Sham Arabic inscriptions in Mediæval art, a testimony to the decorative quality of mere lettering—Further possibilities of ornament in our own alphabet—The value of lettering in ornament, the opportunity for it, the scope in it.

THE technological examinations of the City and Guilds of London Institute reveal that students of building trades are not so intelligent as might be supposed. Taking the subjects as they appear in the report, we find the examiners in "Electric Lighting and Power" remark that "a very large proportion of the failures arise from the unreal nature of the information possessed by the candidates, and from the parrot knowledge which so largely does duty for an acquaintance with the subject. Candidates who cannot give simple answers to quite elementary questions in the technics of the subject, and waste their energies in calculating to many places of decimals numerical deductions from data having only three significant figures, cannot be regarded as qualified to receive certificates of efficiency in this branch of engineering." In "Plumbing" it is said that "very few of the candidates appear to possess any knowledge of the most elementary principles of hydrostatics," and "after a careful revision of the papers it would seem that the instruction mainly consists of learning by rote, and that the majority of teachers make little effort to encourage observation on the part of their students, or to verify by means of simple experiments the various principles underlying the work of the plumber." In some centres there are signs of an improvement in the answers given in the ordinary grade of "Carpentry and Joinery," but the written and graphic answers in honours are not equal to the standard usually attained. The candidates in "Brickwork and Masonry" seem to have no idea why they do certain things; only one was able to say why the ordinary method of striking joints is adopted by brick-

layers. There is a frequent use of difficult words, of which the candidates apparently do not understand the meaning. In no cases did candidates give definite rules for bonding brickwork. It would appear that in many instances the candidates have lacked good, practical, systematic teaching. If an investigation could take place, we are afraid it would be found that the competitors who are so weak formerly went through the processes of the schools of the Science and Art Department. The defects pointed out by the Institute examiners are exactly those which are recorded in Blue-Books as results of the official system of practical education.

THE question of apprenticeship has arisen in the Potteries district, and has had to be considered by Sir WILLIAM MARKBY, the arbitrator appointed by the Board of Trade. The master builders are somewhat uneasy since County Court Judge JORDAN decided that a master was almost as responsible for his apprentices as for his own children. A member of the Masters' Association has had to pay 400*l.* or 500*l.* as damages because one of his apprentices met with an accident. The National Association accordingly issued an indenture of apprenticeship so framed that it would free the master from such liability. The only question was whether it would be good in law. If it was, the masters would have no objection to bind apprentices. On behalf of the men Mr. R. WARD said they did not ask the masters to do the impossible. The arbitrator said he could not decide on the form of indenture to be used, but he should decide whether apprentices should or should not be bound. He should also alter the rule so that no new apprentices should be taken in excess of the number allowed, but that those who were bound should be permitted to remain even when the number of men had dropped below the stipulated proportion. It was agreed that if the arbitrator should rule in favour of apprentices being bound, the decision should not be acted upon until August 1, by which time the masters would know whether the form of indenture was good in law. The masters agreed in the meantime not to interfere with the present arrangement.

As was to be expected, HOLBEIN rules in the Tudor Exhibition, which is now open at the City Art Gallery, Manchester. There are several portraits by him, the most pleasing being the *Duchess of Milan*, which belongs to the Duke of NORFOLK. One of his most characteristic portraits is of the third Duke of NORFOLK. It is superior to the portrait of HENRY VIII. The king's head was one of those which are hard to paint on account of the excess of animalism and, moreover, the artist could hardly be at his ease before a subject who had so many ways of expressing dissatisfaction with a portrait. Another interesting portrait is Archbishop WARING. The Duke of DEVONSHIRE has lent some drawings which originally may have been as valuable as those in Windsor Castle, but they have suffered by the operations of a later artist.

THE annual general meeting of the Institution of Civil Engineers was held on Tuesday. The most important matter which occupied attention was the alteration of the by-laws so as to supplement the existing regulations by the introduction of a test, by examination, of the general and scientific knowledge of candidates for election into the class of associate members. A general conference of the Institution is to be held in London on May 25, 26 and 27, which it is hoped will satisfy a need that has been felt in an increasing degree with the expansion of the Institution. Including associates and students, the total number on the books at the end of March was 7,090. The year's income amounted to 22,285*l.* 8*s.* 10*d.*, and 15,417*l.* was received towards cost of new building. The expenditure of the year was 40,394*l.* 8*s.* 9*d.*, of which about one-half represents normal expenses, the balance being incurred principally in connection with the new building. It is anticipated that the final stage of the operations contingent upon the rebuilding of the premises will be reached during the recess, when the arrangement of the large and ever-increasing stock of publications and documents will be completed.

## ARCHITECTURE AT THE ROYAL ACADEMY.

THE contents of the architectural room in this year's exhibition of the Royal Academy corresponds in character with the exhibition if taken as a whole. There is, perhaps, no work of commanding attraction which cannot easily be forgotten; but, on the other hand, there are many which have much interest. Architecture as well as painting is above the average. The young couples who will use the room during the ensuing months have reason to feel indebted to the architects and designers who have been at so much expense to make the walls more agreeable to occasional glances. It is, of course, for the sake of those occasional and happy visitors that the hanging committee have introduced so many coloured examples of ancient architecture and modern decoration. The Academy is supposed to present examples of living art. On that account it would be considered very absurd to introduce copies of masterpieces in either sculpture or painting among modern examples. In the architectural room an irrational exception is always made. The committee would say we cannot expect our young visitors to exert themselves sufficiently and bestow attention on modern buildings; but about antiquity there is a hazy sort of romance which is in keeping with their feelings. It would be more advantageous for some of the artists if their drawings were found elsewhere. Mr. BREWER's beautiful pencil drawing of the Choir of Bamberg Cathedral should be seen in the black-and-white room. Mr. MALLOW's West Front of St. Gilles, Provence; Mr. H. C. CORLETTE's series from the Abbey Church, St. Savin; Mr. NICHOLSON's Portal, St. Saviour's, Dinan; Mr. HENDERSON's Italian Views, &c., would be more apposite elsewhere than where they are seen.

The modern buildings are varied, and it is not easy to group them. They suggest, in the first place, that Queen Anne is dying, if not already defunct. The tendency is to recur to English models of an earlier time, or to those in France or Italy. The number of churches indicates the efforts which are being made to elevate even the humblest classes; at least one-third of the drawings are ecclesiastical. The churches are mainly of an inexpensive kind, and there are very few among them which are not Gothic. Country as well as Metropolitan architects are represented. Dublin, Manchester, Liverpool, Birmingham, Leeds, Dundee, Nottingham, Aberdeen, Bath, Lancaster, Leek and other places can claim a share in the collection. We shall not attempt any classification, but glance at the drawings in the order they are presented in the catalogue.

We have first a few small but excellent churches by Messrs. G. H. FELLOWES-PRYNNE, E. M. BRUCE VAUGHAN, TEMPLE MOORE, and CLARK & HUTCHINSON, in which the simple rectangular plan is avoided, and there is nothing monotonous in any of them, yet all are cheap. The Hedgehog Inn, by Messrs. BREWILL and BAILY, which is their only contribution, is suggestive of cosiness by the windows, which are broader than long, and the well-sheltered porch. The Seaside Hotel in Cornwall, by Messrs. ROGERS, BONE & COLES, from its size must belong to some out-of-the-way village. The County Hotel, Salisbury, by Mr. E. DORAN WEBB, appears to be placed over a stream, and its position helps to increase its picturesqueness. The Granite Presbyterian Church, Putney, by Messrs. J. C. T. MURRAY & C. E. MALLOWS, resembles a village church, with the exception of the tower, which makes it suitable for its suburban position. The First Lodge, Lea Park, by Mr. PAXTON WATSON, has a gateway with rooms near it forming a group, and is very suitable for its purpose. Mr. THOMAS GARNER's new House at Hampstead is somewhat Elizabethan in style, the large porch being the most important feature. Mr. CUTLER's Vicarage, Epping Forest, resembles one of those pleasing houses which he introduced in his last published collection of designs. The new schools for the French Protestant Church of London, by Mr. ASTON WEBB, appear to be a private house or offices, but the inscription announces the purpose. The two cornices give shadow and the bell-cot imparts variety to the roof, while the pilasters remove the flatness of the front. From the position in which it is hung the view of Her Majesty's

Theatre, Haymarket, by Mr. C. J. PHIPPS, appears as if it must weigh down the lower storey. It is French Renaissance, and would pass as a work of a student of the Ecole des Beaux-Arts. The building is undoubtedly an improvement to the locality. It also suggests the advantage of competition in every department of architecture. The Royal Music Hall, Holborn, by Mr. ERNEST RÜNTZ, is an endeavour to impart good style to a kind of building in which vulgarity is supposed to be allowable. The contrast with its predecessor is remarkable. But in the Empire Palace of Varieties, Middlesbrough, the architect had more scope, and he has produced a building which is novel as well as graceful. The Artisan's Room, by Mr. BARRY PARKER, should be accompanied by an estimate of cost. We hope the London County Council will not be inspired by it to undertake new feats in building luxurious homes for their humble constituents.

The Passmore-Edwards Library, St. George's-in-the-East, by Mr. M. B. ADAMS, is more of a reading-room than a library, for in it the plan devised by PANIZZI has been followed on a small scale. The façade is remarkable for the extent in which curved lines have been used, and if compared with its severe neighbour, the vestry hall, it may be said to be alluring, which is an advantage in such a district. The church of St. Peter, Hornsey, is one of Messrs. J. BROOKS & SON's effective churches which have no towers. Two spirelets serve as belfries; the details are marked by much breadth, and there is no striving after novelty. The new nave and chancel of Yiewsley Church, by Mr. C. A. NICHOLSON, includes a rather remarkable tower. Mr. G. A. LANSDOWNE's mission building is very plain, but is redeemed by the large window. The design for a hillside church by Mr. C. L. BRIERLEY does not appear to be as suggestive as those prepared some years ago for the Bishop of CARLISLE by Messrs. PALEY & AUSTIN. Mr. LACY's screens and decoration for All Saints, Cambridge Circus, is rather indefinite in style, the architecture being subservient to the painting and inlaying. Mr. BRIGG's house at Quarry Woods, Marlow, has the advantage of a long balcony on which the bedrooms open, but on the ground storey it would have been advantageous if the drawing-room was not a repetition of the dining-room. In Mr. J. J. SHAW's bronze gates the figure is largely employed, and there is much richness in the composition. Mr. J. C. WATT's design for a mausoleum is neo-Grec in detail, although a dome is employed. Such a structure would be an interesting addition to a metropolitan cemetery. In the new church of St. Stephen, Nottingham by Mr. W. D. CAROE, flat curves have been employed for the window heads, and form a contrast with the bays of the nave, but we imagine the buttress introduced at the west end will be a disturbing element. The extensions, Panmure Arms Hotel, Edzell, by Mr. T. M. CAPON, with other drawings of northern buildings, will suggest that the peculiarities of the Scottish style are no longer in favour with architects or their clients. It is a good type of country hotel, in which an excess of repetition is avoided. St. Peter's, East Grinstead, is a small and severe Romanesque church, but the tower is so large as to suggest that Mr. WALTERS originally thought of making the building a tower. The Passmore-Edwards Settlement, by Messrs. SMITH & BREWER, is a very plain red brick building, but without any appearance of a prison or a workhouse. In St. Magnus, Bessingby, Yorkshire, Mr. TEMPLE MOORE combines a small low tower and spire of excellent proportion with the body of the church in a pleasing way. The houses at Hampstead by Mr. JAMES NEALE form a substantial group, with rooms that must be all well lighted from the capacious windows and are no doubt commodious. The design for church at Exeter by Mr. C. A. NICHOLSON has an excellent tower, which would probably look better in masonry. Mr. C. SPOONER has produced a quiet and suitable church without the aid of any tower. Messrs. SILCOCK & REAY's country house, Bath, is a very large Elizabethan building which should have a grand park around it. The difficulty is to some extent met by the introduction of a terrace with balustrades separating the ground from the public road, but there is apparently no point of view available from which the building would appear as it ought to be seen if judged properly.

(To be continued.)

## THE WATER-COLOUR SOCIETY'S EXHIBITION.

THE first glance at the exhibition of the Royal Society of Painters in Water-Colours is enough to show that new ideas are struggling against those which gave character to the art. There is possibly an error in suggesting that what now appear as novelties were unknown to the founders of the Society. The Council have prefixed to the catalogue a memoir of JOHN VARLEY, which is taken from Mr. ROGET's book. But it would have been more appropriate if they had introduced some of Mr. VARLEY's precepts instead of an account of his weakness in borrowing money at thirty-five per cent. That fine artist was not an advocate of stereotyped practices. He opposed all those who "too rarely consult their own original impressions of a subject, but rather depend on imitations of works which, though justly entitled to respect from their possessing many valuable qualities, have nevertheless faults in practice contrary to sound principles, and which, instead of avoiding, they often use as sanctions or authorities for their departure from the pure and simple impressions derived from nature alone." In these words we have an apology for Impressionism so long as it is of a pure and simple kind. Another of his recommendations was that landscapes must appear to be executed with despatch, for "while the deliberate progression of the painter in oil may be compared to Philosophy, the practice of landscape in water-colours must assimilate to Wit, which loses more by deliberation than is gained in truth." JOHN VARLEY's words might be taken as a warrant for novelties in practice. But can it be supposed he would approve of such a departure from precedent as Mr. ARTHUR MELVILLE's *Spanish Bull Fight*? We may compare it to a piece of music which depends for interest on its pauses. The blank space in the drawing exceeds the part assigned to figures; indeed, the blank becomes as it were more marked by the occasional introduction of a head or a hat. If the view represented the time prior to the fight when the best seats were empty, we could understand it; but it does not produce the sensation of a time when all thoughts have one direction; rather it suggests a drawing that was well commenced but was never completed. Nor can we believe that VARLEY would rejoice in Mr. CLARENCE WHAITE's *St. George and the Dragon*, in which the monster emits a body of flame that is enough to consume a troop of knights and princesses, or the *Lot and Two Angels*, by the same artist, which indicates that celestial robes are dyed in colours as hard as any extracted from coal tar. To our minds Mr. WHAITE's *The Wrong Path* is preferable, although evidently it was intended to produce the effect of an oil-painting on the gazer. Mr. ALBERT GOODWIN's *The Jumna and the Taj Mahal* is as sultry as can be desired, and it was daring to suggest that sky, land, water and buildings were alike inflamed. But why must he jeopardise the future of his delicate Swiss drawings by so persistent an employment of the scraper? It may be problematic whether water-colours fade, but a few days' exposure of the *Amsteg, St. Gothard* without glass would mar its effect. Mr. MARKS knows how to justify the title of a picture, as becomes so practised an illustrator; why has he found it necessary to employ large capitals in gold to indicate which is which of the two figures in his *Envy following Merit*? In all the preceding cases innovation does not signify improvement, and the majority of visitors are likely to enjoy the old-fashioned examples with more zest in consequence.

Sir JOHN GILBERT has another characteristic work, *A Standard Bearer*. It is all in opaque colours, and the buffs especially are very dirty. The blue standard is harsh and disagreeable, but the effect is striking. In VARLEY's time the difficulties of the draughtsman arose from the peculiarities and defects of the paper. Some credit is due to the maker of the sheet employed by the President, for it has to sustain a very heavy load of colour. Sir JOHN's *Cedric's Pledge*, from "Ivanhoe," recalls one of his drawings. As usual, he is indifferent to the archæology, for SCOTT certainly is silent about so large an expanse of white linen on the tables as appears in the drawing. The Deputy-President has wisely restricted himself to two small portraits of Mr. WATTS, R.A., and Mr. B. BRADLEY, which are as vigorous as if they were on larger scale.

Mr. CUTHBERT RIGBY has some drawings from the North of England lake district which are delightful, not only for their quietude, but from the success with which atmospheric effects are represented. Mr. S. J. HODSON has evidently painted his three subjects on gloomy days, and in consequence the buildings in Goslar and Hulberstadt appear heavier than is usual with this painstaking artist. Mr. WALTER FIELD, in his *Way to Borough Marsh* and *Hampstead Heath*, also shows the influence of the weather and the absence of sunlight. The Heath, in consequence, is hardly recognisable, it is so sombre. Mr. WILMOT PILSBURY this year paints landscapes only, which are very careful in all their details. The three drawings by Mr. BIRKET FOSTER are welcome additions. There is less conventionality than usual. Mr. W. CALLOW in productiveness has surpassed the other members. Objections may be raised against his system of outlining with a pen, and the colours employed seem occasionally to have been put in from recollection, but in suggesting the character of foreign buildings he comes nearest to PROUT. This year there is no abatement of dexterity. Official duties do not seem to have made Sir E. J. POYNTER's hand more light. On the *Lake of Geneva* is an honest endeavour to be accurate, but the landscape forms are too severe. They are apparently as puritanic as the citizens. Mr. M. HALE's *Winter Twilight* is a difficult subject, for it shows a street with the shops brilliantly lighted. The *Italian Landscape* by Mr. R. LITTLE is of course spotty, but the colour is fine, and there is a suggestion of the Southern atmosphere. Once more Mr. J. W. NORTH has an autumn scene, *King Arthur's Pool*, but with the variation of a waterfall. The colour, we need hardly say, is splendid. Mr. H. S. HOPWOOD has three interiors, the most successful being *A Whittly Jet Worker*, a man in a garret lighted from the roof working at his lathe. Mr. T. M. ROOKE's church buildings will be preferred to his *Clytie* and *Daphne*. He is one of the best of the Society's architectural draughtsmen. Mr. W. COLLINGWOOD is in force this year with Alpine scenes. Mr. H. M. MARSHALL is competing with Mr. WYLIE in below-bridge scenes; the best of them is the *Old Essex Wharf, Limehouse*. There is some novelty in Mr. S. P. JACKSON's *Stonehenge*, for the ground seems covered with hoar frost and there is a warm sunset at the back. Mr. TOM LLOYD has two winter scenes showing a house lighted up from within. His *Waterlilies* and *Primrose* are, however, in the style which his name recalls. Mr. NAPIER HEMY, as usual, has some excellent fishing-pieces, of which *A Gale, Scilly*, is the finest. Miss MILDRED BUTLER's *Banquet*, showing a number of pigeons collected around some golden grain, is a spirited drawing. Her *Toll from the Turnip Cart* and *Shine and Shadow* are further evidence of the lady's importance as an addition to the Society. Mr. JOHN PARKER has abandoned his village maidens and his pair of mediæval poachers in *Who Comes? Burnham Beeches in the Olden Time* is the most effective drawing he has produced of late years. But the outlaws are only accessories to the splendid trees. Mr. CARL HAAG's *Nubian Harper* is represented with his customary precision, and is novel in appearance. Mr. E. F. BREWTONALL has attempted a most difficult subject in the *Fisherman and the Genie*, which is an admirable illustration of the Arabian Nights. The artist is no less successful in his landscapes. The two Scotch views by Mr. COLIN B. PHILLIP, *The Iron Road* and *The Island of Rum*, will bear comparison with any similar scenes which have appeared in the Gallery. He is a strong rival of Mr. R. W. ALLAN, whose *Fresh from the Sea* is true to nature. Mr. GEORGE CLAUSEN has one drawing, *Earth and Sky*. The earth is true enough, but the puffy clouds in the sky seem to be only a transient phenomenon. Mr. WAINWRIGHT's *Here's a Health to the King* is not happy, but with a different face the costume and accessories would pass. Another disappointment is Mr. GLINDON's *Monastic Dinner*, which is commonplace in subject, and the figures have not the characterisation which the artist has so often displayed. Miss C. MONTALBA has three views in Venice in her usual style. Mr. A. R. HUGHES should be represented by more than one drawing. His bust, *Jacques*, a Shakespearian study, is not enough to satisfy the artist's admirers. Mr. A. E. EMSLIE is more vigorous than usual in his view of *Barnet Fair*.

The Water-Colour Society labours under the disadvantage of having no real competition. Every member is

supposed to have a field of his own which he can cultivate without any disadvantage to his neighbours. Some members are so familiar with their subjects, we often wonder it is not announced they have made their drawings with their eyes closed; that result must be expected so long as the Society is a close corporation without any expectation of reform. If we remember these facts and make allowance for them, the quality of the Society's exhibition will not appear to be so dubious as it would be to those who were not aware of the happy position which the members possess.

## STREET LIGHTING BY ELECTRICITY.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

THE subject of the better illumination of the streets is now receiving the careful consideration of borough surveyors. The actual benefit of an increased illumination can hardly be estimated, but it is undoubtedly very large in important thoroughfares, and the difference between well-lighted streets and poorly-lighted ones may make all the difference in the trade of a town. What really is required is a fairly equal distribution of light. This fact is being realised at the present time, and attempts are being made to increase the illumination, retaining often the gas lighting also. The object of this article is chiefly to show that, as the standard of illumination is increased, electric lighting comes to the fore as the cheapest and most satisfactory.

In order to obtain a satisfactory result, several points must be taken into account. It cannot be stated that a lamp of a certain candle-power will afford sufficient illumination for a given length of street or a certain area. The conditions as to the nature of the walls of buildings on either side, the width of the street and its course, whether straight, curved or hilly, the height the lamp is to be placed, and its appearance, must all be considered very carefully; but, given the same street, a comparison may be made between two methods of illumination.

Referring to the positions of the lamps, we find the lamps in some cases in the centre of the road, in others alternately on either side, and often a combination of the two.

As a basis of illumination, it may be taken that the illumination given by bright moonlight is the least that ought to be allowed as good. Mr. A. P. TROTTER found that this illumination is one-thirtieth of that given by a standard candle at a distance of 1 foot (the candle-foot).

The use of incandescent electric lamps is not appreciated, especially in main streets. The reason for this is that when electric lighting is introduced into a town the inhabitants expect a more powerful light, and are disappointed at the result when incandescent lamps of comparatively low candle-power are used. It is, however, often advisable to use them in side streets, and especially when the contract with the gas company is being ended, as in this case and others where the mains are laid in residential and side streets a great saving can usually be effected if the local authorities are the owners of the works. In any case, the lamps must be neatly and carefully erected, and scientifically shaped reflectors and diffusing globes should be used. The mere placing of incandescent electric lamps in ordinary gas lanterns is apt to look ridiculous. With lamp standards already fixed, the distribution of light would be the same practically with an electric incandescent lamp as with a gas-jet of equal power. For lamps burning all night electricity can be supplied at a rate unapproachable by gas, as the cost of producing electricity under these conditions is extremely low, while the cost of gas is not affected by the time of burning to any large extent.

The comparisons hereafter made refer to continuous current arc lamps, as they are preferable for street work. An alternating arc is in the first place less efficient, and secondly, the light is distributed in an unsuitable manner, half of it being thrown above the horizon, whereas with continuous currents nearly all the light can be thrown below the horizon. It may be taken that with alternating current lamps the cost of lighting will be about 50 per cent. above that with continuous. When a high standard of illumination is desired, a fair comparison may be taken

between a lamp taking 50 cubic feet of gas per hour, and giving a mean spherical candle-power of about 150, and an electric arc lamp taking 10 amperes, and giving a mean spherical candle-power of about 1,150.

The 10-ampere arc lamp can be kept in order and supplied with carbons and current at an annual charge of 26% if run all night, *i.e.* 4,300 hours per annum. The gas lamp will cost about the same per annum, assuming gas at 2s. 2d. per 1,000 cubic feet, and allowing 2d. per annum for cleaning, &c.

In comparing the illumination produced on the ground, or on a plane say 5 feet 6 inches above the ground (the average level of the eye, which is the one required most often) by these two forms of illuminants, there are several terms which must be defined. The unit of candle-power is the intensity of the light given out by a definite candle measured at, say, 1 foot from the source. The candle-power of any source of light at any point varies inversely as the square of the distance of the source from the point. The unit of illumination on a surface is the illumination produced by a standard candle placed at unit distance, say 1 foot, from the surface. This unit is called the candle-foot. The difference between candle-power and illumination (candle-foot) is that the former is practically the illumination which would be produced by the lamp at a fixed distance (1 foot), and the latter the candle-power of a lamp which, if placed at a distance of 1 foot from the surface, would produce the same illumination as that to be measured. For instance, 1,000 candle-power lamp 100 feet (direct) from the surface produces an illumination of

$$\frac{1,000}{100^2} = \frac{1}{10} \text{ candle-foot, a very small amount for such a large lamp, it may be said.}$$

Returning to the particular case. It will be found that a 10-ampere arc lamp, placed on a post 18 feet high, will produce  $\frac{3}{4}$  a candle-foot maximum illumination; hence the candle-power in this particular direction is about 400. The candle-power is much higher in a direction corresponding to a further distance from the post, but the illumination does not increase with the candle-power, owing to the rate at which the actual distance of the spot from the lamp is increasing. With the gas lamp the candle-power is practically uniform in all directions, and consequently the maximum would be near the post, which would be about 12 feet high. Therefore the maximum illumination would be higher than with the arc, *i.e.* one candle-foot. This is due to the post being shorter. At a distance of 100 feet from the foot of the post the arc will give an illumination of .023 candle-foot, while the gas lamp will give about .014 candle-foot, or less than half, while at a distance of 30 feet the arc will give .67 of a candle-foot, while with the gas only .13 candle-foot is obtained. In fact, the illumination diminishes very rapidly with the gas lamp, and less rapidly with the arc. It will be found that from two to three gas lamps of this description (depending on the nature of the street) can be replaced by one 10-ampere arc. Taking the figure 2, then, to get the specified minimum illumination ( $\frac{1}{30}$  candle-foot, moonlight), the same average illumination and approximately the same maximum, in the case of arc lamps they would need to be 120 feet apart, and in the case of gas lamps they would be 60 feet apart; in fact, the cost of lighting the area to approximately the same level (a high one) would be 72% per annum in the case of gas and 36% in the case of an arc lamp. If the gas lamps were of lower power, and more of them in the area, the arc lamps would replace them in the same proportion for the same average illumination. For example, one 10-ampere arc would replace two 150 candle-power, four 75 candle-power, six 50 candle-power, and twelve 25 candle-power gas lamps. With the lower candle-power gas-burners, more evenly distributed, the minimum illumination would be higher and the lighting more uniform; but the lower efficiency of the smaller burners and the increased capital outlay, cost of cleaning, &c., balances this advantage, and the cost would be in the same ratio, *i.e.* the cost of gas-lighting at least twice that with continuous-current arc lamps.

If the lamps are placed further apart, the arc lamps must be raised considerably, in order that the parts further from the lamp shall receive some light.

If the streets are wider than half the distances between

the posts (60 feet for arcs and 30 feet for gas), it will be necessary to place lamps in the middle of the street, so that the minimum shall not fall beneath the limit imposed (moon-light). With lamps of lower candle-power it is necessary to place the lamps nearer together to obtain a reasonably high minimum, and the average is consequently more uniform the maximum being less.

The fact that an arc lamp gives very much less light near the horizontal than below it handicaps it for this work, *i.e.* large centres of light at considerable distances apart, as the minimum becomes so low, and the solution of the difficulty will undoubtedly be found in smaller lamps placed nearer together. Two 5-ampere lamps would be much more effectual from this point of view than one 10-ampere lamp, although the average illumination would probably be less. Lamps of less than 5 amperes are never used for street lighting, as they are not reliable, and this limits the extent of the use of arc lamps to fairly high illumination work, where they can be near together.

If small arc lamps of about 100 candle-power could be made, burning a long time (to reduce attendance), to work satisfactorily, gas lighting would be at once doomed, for in that case the electric arc light could be used for a low illumination such as is required in most cases. The arc lamp is, light for light, only one-third as expensive as gas or incandescent electric lamps to run, assuming the average costs for gas and electricity, and would naturally supersede them; it is the low illumination between the posts when they are far apart that restricts its use. There are at the present time several attempts to produce such lamps, and no doubt they will be obtained in time, and then electric street lighting will be as much cheaper in our small towns, compared with other illuminants up to the same standard, as it is now in our cities.

The difference between the distribution of light with an arc lamp and an incandescent electric or a gas lamp is that with the two latter the candle-power is uniform in all directions, and with the former the distribution is roughly as follows, assuming the maximum candle-power to be 1,000:—

Angle with the Horizontal.	Candle-power.	Angle with the Horizontal.	Candle-power.
0 deg.	200	40 deg.	1,000
10 "	400	50 "	800
20 "	600	60 "	457
30 "	875		

The original practice was to place arc lamps very high when the area illuminated had to be large, so that the furthest point should be brought at a greater angle from the horizontal, where the candle-power is greater. This practice is now going out and steps are being taken to increase the candle-power in the more horizontal portions. This is done by lengthening the arc and increasing the voltage, and by the use of reflectors and diffusing globes to alter the distribution of light.

In narrow streets the lamps are often suspended from the houses on either side, and often light arched girders are used to support the lamp and to allow of its being cleaned by drawing it to one side without interfering with the traffic. This latter is done in the City of London and at Brighton.

Respecting the relative capital cost of erecting gas and electric lamps there is very little difference, and for high candle-power lamps the cost is less with the electric arc, and with the low candle-power lamps the cost is about the same, whether gas or electric are employed.

Incandescent gas has not been considered in this article for the reason that although the cost for gas with the same illumination might be less, the cost of renewals to mantles, the increased capital cost and the extra attention required will bring the total cost to about the same level as with ordinary burners. In many places where it has been tried the amount of attention required and high cost of renewals due to vibration and wind have proved against it. Even at its best it cannot compare favourably with arc-lighting for high illuminations, and incandescent electric lamps will replace incandescent gas burners in street lamps with a saving for the lower illuminations.

In conclusion, it should be remembered that the efficient lighting of the principal streets will give greater satisfaction and receive more general approval than the lighting of a large area in an inadequate manner.

## HOT-WATER HEATING.\*

IN a great many ways the Americans are proud to keep up English institutions, but it looks as if one of the most sacred—the English fireplace—is to succumb to their inventions. "My own fireside" is supposed to be as peculiarly English as the word "home." Generations of schoolboys can always understand, more clearly than most other incidents related in English history, the comparison which the old Thane made before PAULINUS in the reign of King EDWIN, when man's life was said to resemble the passage of a bird through a hall, and which had been attracted by the blazing fire on the hearth. Even beasts and birds were supposed to appreciate the open fire. We need hardly say that the character of English buildings has been affected by the necessity of providing open fireplaces and big chimneys. In copying Greek and Italian models; it has been difficult to introduce chimneys that will be in keeping with the rest of the design, but although they were made to assume the forms of vases or ornamental appendages, it was compulsory to avoid the omission of them. A change in that respect appears to be inevitable. According to Mr. DYE, "The day cannot be far remote when the majority of residences of fair size will have a hot-water heating plant in them, and the saying about an Englishman's love of an open fire and its cheerful blaze will be extinct." As a consequence, we must expect modifications in chimneys. Smoke pipes will be often substituted for them, and, as our author suggests, "will bear tasteful decoration in light water-colours," which last and keep in satisfactory condition. We may even have underground flues. We must, therefore, expect a revolution in planning, unless old-fashioned arrangements are preserved for the sake of effect. In one place we are told about a "well-known engineer in London who, whenever he can, carries a distinct flow and return from the boiler to each floor, and the practice insures excellent results, but is not usually possible for various reasons, such as cost, the appearance of the stack of pipes, &c. No one, however, could find fault with the way in which the apparatus would work." But as the public are beginning to consider that comfort is of far more importance than appearance, it may be assumed that the stacks of pipes and the various appliances for heating by hot water will become the ruling elements, for which, whatever the sacrifice entailed, provision must be made.

Although warming by the aid of hot water is now one of the most essential industries of our time, it is of comparatively recent origin. It was not, we believe, considered of sufficient importance to be represented in the International Exhibition of 1851. In 1859 only three varieties were known to experts, *viz.* KEWLEY'S, the Marquis DE CHABANNES'S, and PERKINS'S. They were not very elaborate in arrangement, as will be evident from the following description:—

The hot-water apparatus, in its simplest form (Kewley's), is on the principle of a syphon. It consists of a long pipe coiled about in the rooms to be heated, and having two legs of unequal length passing down into an open kitchen boiler; the short leg dips just under the surface of the water, and the long leg passes to the bottom of the boiler. As the water becomes hot it rises in the short leg and circulates to the coils in the upper level, where it parts with its heat, and then descends in the long leg to the boiler. The apparatus is not adapted for any great height (not above 14 feet), and the water cannot be heated above 180 degs. because of the tendency to a vacuum.

The second form of the apparatus is that contrived by the Marquis de Chabannes. It consists of a closed boiler, with the two legs of the syphon communicating with a cistern at a high level. These are filled with water, and when the fire heats the contents of the boiler, the hot water rises at once to the cistern, whence it is distributed by coils to the rooms to be heated, and then it descends to the boiler. By this arrangement the temperature may be raised to 212 deg., and the water conveyed to any distance.

The third and only other form of the apparatus is the invention of Mr. Perkins. It is a closed circuit of comparatively small pipes filled with water. About one-eleventh part of the whole tube is coiled in a suitable manner and placed in a furnace at the lowest level. From this a straight tube passes to the top of the building, and thence the pipe descends to the several rooms to be warmed, where it is coiled so as to expose a large radiating surface; from these it returns to the coil in the furnace. An expansion or safety tube is placed at the uppermost part of the apparatus to guard against danger from the too great expansion of the heated water. The temperature of the water in the

\* *A Practical Treatise on Warming Buildings by Hot Water, and upon Heat and Heating Appliances in General.* By C. H. Hood, F.R.S. Rewritten by F. Dye. Third Edition, Revised. London: E. & F. N. Spon, Limited, 125 Strand.

furnace coil may be raised to 400 deg., but the circulation and cooling in the return coils is so great that the water soon falls to 200 deg.; in fact, when the return coils have a radiating surface about ten times as great as that of the furnace coil, it is hardly possible to maintain a temperature above 200 deg.

A glance at our advertisement pages is almost sufficient to suggest how numerous and perfect are the appliances which are now available. The demand would not be even so general as it is at present if there were not benefits obtainable from hot-water heating which can compensate for the sacrifice of the associations connected with the older systems. There are, however, some obstacles which are more difficult to overcome than the loss of the open fireplace. One is the prejudice about the unhealthiness of coils and radiators. It may as well be admitted that almost every element of a house can become injurious to health if there is negligence. Windows and doors are agents in creating colds and other chest diseases. Chimneys and fireplaces may not aid in drawing off with sufficient celerity the dangerous elements which are set free in burning coal. Pipes may turn water into poison, drains can emit deadly gases. In fact, carefulness is required from the occupants of houses, and all parts of the building, from foundations to roof, should be regularly observed if the possibilities of risk to health are to be diminished. If a hot-water apparatus is neglected by those who use it, or if it is set up by incompetent men, there is no reason why it should become an exception to the universal law which makes discomfort and other evils appear as the penalties of indifference. Heat can be controlled, and the interior of a house kept at a uniform temperature by the apparatus. A blessing of that kind would be worth some minor sacrifices, but people who have employed hot-water heating have failed to suffer in any way. Another obstacle is the appearance of radiators. They are not always in the best taste, and some which are supposed to be ornamental are the least satisfactory. But that is a weakness which seems common to many varieties of metal-work. When we see costly bridges which do not gratify the eyes of spectators we must not bear too hard on the makers of apparatus. They have to work under disadvantages. So far as experience goes, radiators cannot be concealed without loss of efficiency. Then there is vigorous competition, which is never favourable to the production of works of art. But it is evident that efforts are made to improve the appearance of radiators. Mr. DYE is surprised that brass is not used, which is so well adapted, and he says he has some in progress which he anticipates will "do much to make hot-water heating more favourably looked on in well-furnished houses, and there is also a probability that other manufacturers will be induced to follow the example set them." Any change of that kind will facilitate the introduction of radiators into private residences.

For hot-water heating in public buildings and houses there is a sort of experimental region such as is not to be obtained in most applications of science, viz. horticultural works. Economy and simplicity have to be studied and the spaces to be heated are not always in the same condition. Mr. DYE has therefore devoted a large part of his book to the peculiarities of heating horticultural buildings, and the subject is worthy attention, although the student may never be called on to design conservatories. In ordinary buildings there can be a choice of apparatus, but they all exemplify the low-pressure or high-pressure systems. Each system has its advocates, but it rests with the architect to make the choice. It is an advantage of Mr. DYE's book that there is no endeavour to bias the reader's judgment. He has apparently carried out a variety of works, and he gives to all the benefit of his experience in a manner that must be considered impartial. For example, in describing his work in a large bank he says the mains were carried along the ceiling of the basement (the radiators were in a crypt below), which was not absolutely necessary, as there was a space between ceiling and floor in which they could be placed. But the architect wished to have all the pipes visible, on which decision Mr. DYE remarks:—

It is certainly desirable to carry pipes, when the length and quantity is considerable, so that they are always visible, for with the best work leakages will occur. The leaks that may show themselves at first testing are of course remedied there and then; but small leaks may develop themselves for possibly a month afterwards—not as a rule, perhaps, but it certainly does happen so occasionally. If a large

apparatus is finished and tested in the summer time, a leak or two may reasonably be expected when the apparatus is set to regular work later in the year. Leaks do not occur perpetually, however, after the system has once been overheated and subject to the trials that a new apparatus is liable to, with probably an unskilled attendant at the boiler.

But there is another aspect of the case, for with exposed mains there is generally a loss of heat, which is an important consideration. Mr. DYE therefore says:—

It is very desirable that the mains be covered, to conserve the heat within them. If this is not done, more trouble and expense is incurred than appears at first thought. Mains are seldom carried in the warmest situations—that is, situations naturally warm—so that they lose a deal of their heat. The flow main, of course, has the hottest water within it, and consequently is in a condition to lose heat the fastest when surrounded by cold air. The loss can be easily calculated, and will be found commonly equal to six radiators doing good work. This means waste of fuel, as a rule, and always delays results when heating up; but most importantly it means serving radiators with water that has been reduced in temperature. When mains are uncovered, or merely encased without packing material, they must be calculated as radiating surface when arriving at the size of boiler to work the apparatus. This may make an extra expense in the boiler greater than the cost of covering the pipes, apart from the better general results the covering ensures. By covering the pipes it is not meant that they have to be totally hidden in cases beneath floors or plaster-work. There are coverings now made that can be put up very rapidly, are as neat in appearance as the pipe itself, and which admit of any part of the pipe being exposed in less than a minute.

The high-pressure system which was introduced by PERKINS in 1845 is not as generally employed as its rival, and its title may have something to do with the difference. In drying-rooms, japanning works and for various other industrial purposes high-pressure heating is almost indispensable. But wherever used the rule in the Building Act must be observed:—"A pipe for conveying hot water shall not be placed nearer than 3 inches to any combustible materials." The restriction does not now apply to pipes conveying steam or hot water at low-pressure, the latter being supposed whenever the pipe is provided with a free blow-off or open expansion pipe. The distinction is enough to increase a prejudice against the high-pressure system, although as the primary purpose of the Building Act is to remove all chances of fire, the precaution is not excessive. The 3-inch limit, however, does not compare favourably with the liberty conferred by the Act in authorising the fixing of a pipe for conveying smoke or other products of combustion at no greater distance than 9 inches from combustible materials. Mr. DYE says the limit is decidedly insufficient with horizontal pipes carried beneath ceilings, especially match-lined ceilings. There is no rule about sweeping, and the pipe, if of sheet-iron, might become red-hot, while earthenware flues are when foul liable to fracture. To increase the security of both hot-water and stove pipes Mr. DYE considers there is nothing better than silicate cotton. He refers to an experiment made "with a thickness of silicate cotton of 1 inch, rather tightly packed, placed tight against a surface at bright red heat, about 1,550 deg., for thirty minutes; at the end of that time the outer side of the material was only about 180 deg., almost bearable to the hand; no currents of air existed to have a cooling influence."

The heated-air system is likewise described in the book. There is no reason to suppose that air becomes deteriorated by the contact with stoves or radiators. The dryness which some people dislike is easily removed. In the Gurney stove, for example, the lower ends of the gills are provided with water troughs; they form an effectual remedy. Mr. DYE considers that "perhaps the most complete appliance for warming air in a central chamber (for distribution by gravity, and not mechanically) is GRUNDY'S 'Calorifer,' and with it humidity is insured by means of an evaporating trough. The advantages of the calorifer have been tested by employment under the most varying conditions, and in all circumstances it has given satisfaction. The Blackman Ventilating Company, by their "double duct" system, are able to supply a volume of warm and cold air which can be regulated to any temperature, and therefore an interior need not be affected by the variations of the external atmosphere in our most variable climate. The number of other eminent firms that have taken up heating is a guarantee of continuous improvement. When it is remembered that there are specialties in the market by MACFARLANE & Co., the Coalbrookdale

Company, HARTLEY & SUGDEN, FLETCHER & RUSSELL, JONES & ATTWOOD, MESSENGER & CO., THE THAMES BANK IRON CO., LUMBY, SON & WOOD (Bellamy), MÜNZING, SHORLAND BROS., KÖRTING BROS., YATES, HAYWOOD & CO., KITCHEN & CO., AMERICAN RADIATOR CO., GENERAL IRON FOUNDRY CO., and many others, we may assume that this country will, in heating apparatus, hold its own against rivals. Mr. DYE's book is so ample in its information as to enable the reader to realise what can be accomplished for increasing the comfort of buildings.

### GENERAL GRANT'S TOMB.

IN the April number of the *Century Magazine* there is an interesting article from the pen of General Horace Porter, president of the Association organised for the completion of the fund necessary for the construction of the monument to General Grant. From the article we learn that, after considering various measures for providing a proper sepulchre, a number of prominent architects were invited to submit competitive designs for a monumental tomb. In September 1890 the Association adopted the plan furnished by Mr. J. H. Duncan, of New York City, for a structure to cost between 100,000*l.* and 120,000*l.* A contract was made for building the foundations, and the ground was broken with elaborate ceremonies on the anniversary of General Grant's birthday, April 27, 1891. General Porter then details minutely the various steps taken to raise funds, and the requisite amount was rapidly subscribed. The work of erecting the tomb was then proceeded with, and the whole is now entirely completed. The event was celebrated with great pomp. As General Porter says:—"Since the transfer of Napoleon's remains from St. Helena to France, and their interment in the Hôtel des Invalides, there has been no similar function that will equal in solemnity and in importance the dedication of the tomb in Riverside Park."

After a diligent search for a suitable stone of light colour, entirely flawless and durable in quality, a granite singularly well adapted for the purpose was found in North Jay, Maine, and this stone has been used in completing the structure. Another difficult matter was the selection of a material suitable for the sarcophagus, and ultimately a porphyry of fine texture and brilliant reddish colour from Montello, Wisconsin, was chosen as most appropriate. To comply with the frequently expressed wish of General Grant that his wife should be laid to rest by his side, a sarcophagus, the exact duplicate of the one now finished, will be provided. The lower portion of the tomb is a square structure of the Grecian Doric order, and measures 90 feet on a side. The entrance is on the south side, and is protected by a portico formed of double lines of columns, and approached by steps 70 feet wide. The square portion is finished with a cornice and a parapet, at a height from grade of 72 feet, and above this is a circular cupola 70 feet in diameter, of the Ionic order. This again is surmounted by a pyramidal top, terminating at a height of 150 feet above grade, or 280 feet above mean high water of the Hudson River. The interior is cruciform in plan, 76 feet at the greatest dimension, the four corners being piers of masonry connected at the top by coffered arches, the crowns of which are 50 feet from the floor level. On these arches rests an open circular gallery of 40 feet inner diameter, culminating in a panelled dome 105 feet above the level of the floor. The surfaces between the planes of the faces of the arches and the circular dome form pendentives which are decorated in high-relief sculpture, the work of Mr. J. Massey Rhind, and emblematic of the birth, military and civic life, and death of General Grant. The sarcophagi will be placed in a crypt directly beneath the centre of the dome. The approach to the crypt is by stairways which give access to a passage encircling the space dedicated to the sarcophagi, which space is surrounded by square columns supporting panelled marble ceilings and entablature. A circular opening in the main floor gives an unobstructed view of the sarcophagi from that floor and from the gallery.

On the death of General Grant there was a widespread desire to have his remains interred at Washington, either in the National Cemetery at Arlington, in the park of the Soldiers' Home, or in the crypt of the Capitol. As every previous President had been buried in the State of which he was a resident, there was an earnest plea put in by the people of New York urging that the place of burial should be the nation's metropolis, the city which the General had selected as his permanent home. The mayor of the city, the Hon. William R. Grace, proposed to the family that if the burial should take place in the city of New York, a suitable location would be provided either in Central or Riverside Park. A week or two before the General's death he expressed some views to his son, Colonel Frederick D. Grant, in regard to his burial. The disease had made such progress that his power of articulation had almost ceased, and it was only by a supreme effort that he could whisper articulate words; he therefore used a pencil and paper

to communicate with those about him. When he began to write, his son, who had remained by his bedside for many months and whose filial devotion had never relaxed, bent over his father to see what he was writing. The General named Galena, Illinois, his old home, then paused and shook his head. He then wrote West Point, but expressed the fear that the rules governing interments there would prevent the burial of Mrs. Grant by his side. He finally referred to New York, where he had found such kind and devoted friends, but added that he wished no place selected where his wife could not be buried by his side. He was apparently attempting to write more, but a paroxysm of pain seized him and the subject was not renewed. As New York was the last place he had indicated, the fact created a sentiment in favour of that city, as it had been apparently the General's final request. The family expressed a preference for New York, as it was their home; and with their assent the site of the present monument in Riverside Park was selected. It furnished an ideal location for the erection of a monumental tomb, the ground being on the bank of the Hudson, one of America's noblest rivers, at a height of about 130 feet above the water. It was seen that a monument of suitable height would be visible from prominent parts of the city and from points many miles up the river.

### DUNBAR PARISH CHURCH.

THE parish church of Dunbar, which has just undergone extensive alterations and improvements, was built seventy-seven years ago and was opened for public worship on April 20, 1821. In external design it is a very fair example of what could then be accomplished at that early period of the revival of our ancient Gothic architecture. But the moment one passed into the interior it was thoroughly disappointing—a large square space with a gallery all round. That, however, was the fashion of the time, and was, indeed, accepted by many as characteristic of Presbyterianism. As a better knowledge of ecclesiastical architecture spread it was felt more and more that the interior of the church was quite out of keeping with its beautiful exterior, and as a result of this more enlightened view the whole of the interior has been removed and the area subdivided into nave and aisles by means of stone arcades of five arches each. A semi-octagonal apse has been thrown out at the east end, opening into the nave with a chancel arch of moulded stonework, having a minister's vestry on one side and an organ chamber on the other. In the apse are three large windows, the two from the old church being of stained-glass to the memory of the late Admiral Hay, of Belton, and the late Mr. Drysdale, of Castlelaw. The third is about to be dedicated to the memory of the late Dowager Duchess of Roxburghe. The nave ceiling has been raised, bringing into view a part of the carpentry of the main roof. The tracery front of the old gallery has been worked into the front of the new one at the west end of the church, and the steps of the old stairs have been worked into the gallery staircases contrived in the two western turrets, where doors of egress are also provided. The fine old pulpit of the church has been retained, and placed against the south jamb of the chancel arch, the baptismal font occupying a corresponding position at the north jamb, with the communion table between on the centre of the apse. The splendid Dunbar monument now stands on the floor level of the church, against the east wall of the north aisle, completely restored, and has never been seen to such advantage since the day of its erection 270 years ago. All the windows have been double glazed, the inner glass in quarries of a light amber tint. Gas has been introduced, the nave being provided with eight corona lights, and a large one of burnished brass hangs from the apse ceiling over the communion table. The whole of the work has been executed from the designs and under the supervision of Messrs. W. & J. Hay, architects, of Liverpool. The contractors for the mason and joiner-work were Messrs. Robert Hall & Company, Galashiels; for the slater and plaster-work, Messrs. Archibald Aitken & Son; for plumber, gasfitting and heating apparatus, Messrs. Melville & Son; for painting, Mr. Mackenzie—all of Dunbar; and for glazing, Messrs. George Lindsay, of Edinburgh. To Mr. W. G. Stevenson, sculptor, R.S.A., was entrusted the important work of taking down and reconstructing the Dunbar monument. The two stained windows were taken out and replaced by Messrs. Ballantine & Gardiner, of Edinburgh. In place of the old cracked bell, one of nearly double its weight has been provided by Messrs. Bryden & Son, of Edinburgh. The cost of the whole work will be somewhere about 4,500*l.*

**The Next Ordinary Meeting** of the Society of Engineers will be held at the Royal United Service Institution, Whitehall, on Monday, May 3, when a paper will be read on "Automatic Gas-station Governors," by Mr. Henry O'Connor, vice-president.

## NOTES AND COMMENTS.

It is not known to all Parisians that at least one-third of Paris is built over caverns which were formed by the removal of the fine building stone which was afterwards employed for the construction of the city. It becomes a serious question whether the stability can be maintained continually. As one means of obtaining definite knowledge on the subject, the Prefect of the Seine has given instructions for the preparation of a plan of the former quarries. The precautions are of old date. In 1770 several buildings sank into the cavities, and officials were then appointed by Louis XV. to watch all signs of weakness. There are no less than five groups. The first is under the ground where the Arc de Triomphe stands. In the old quarries several massive piers have been erected in order to increase the strength of the strata. The second group is on the left bank of the Seine, and among the establishments which have to be supported are the Jardin des Plantes and the Halles au Vin. The third group passes under the Boulevard de l'Hôpital. The official information about those quarries was burnt in 1871 in the Hôtel de Ville. There is less confidence about the stability of the strata than in other parts. The fourth group extends from the Bastille to the Forest of Vincennes. In this group no less than 2,520 piers have had to be set up. The fifth group stretches beneath Montmartre, the Buttes Chaumont, Pere-la-Chaise, and into the country. The piers are countless in this part. It is fortunate that Paris is not subjected to terrestrial disturbances, or there would be endless work for builders. A great many inspectors are employed to perambulate the galleries, and they are paid at the rate of five francs a day.

Mr. WHISTLER loves a joke, as becomes so wise a man, but we do not think he contemplated the production of one when he proposed to send three paintings to the Salon du Champ de Mars, having for titles *Green and Violets, Rose and Grey, Blue and Gold*. In the catalogue they are numbered 1,257, 1,258 and 1,259, but on the opening day of the exhibition they were not to be discerned. According to one critic, the paintings were described as exquisite; while another objected to the artist's persistence in employing greens, violets, roses and greys. The descriptions were no doubt prepared after visits to the artist's studio. If they do not appear in the exhibition, the public will be the losers rather than Mr. WHISTLER, who is one of the few men who can be as independent of the Champs Elysées as of the Champ de Mars.

THE report to the Governors of the City and Guilds of London Institute for the past year's work has appeared. One of the most encouraging sections of the Institute's work is the South London Technical School. As some indication of the influence which the modelling department of the school has exercised and is exercising on plastic art, it may be mentioned that in the sculpture section of the Royal Academy exhibitions last year, no fewer than twenty-one of the exhibitors were past or present students of the South London School. In the competition for the Institute's Sculpture Studentship, open to students who have attended the modelling classes regularly for three years, seven designs were submitted, and six of them were of high excellence, so much so that the judges, who gave an exhaustive criticism on each, came to the conclusion that some special recognition should be made of the competition. On the recommendation of the judges, the committee have further determined to offer for competition among the past holders of the Sculpture Studentship a Travelling Studentship of 60%, to enable the winner to see the best works of architectural decoration in Belgium and France. The modelling classes have been attended by thirty-one students. The course of instruction in the house decoration class includes the treatment of walls and ceilings, panels, friezes, dados, graining and marbling, and other sections of the decorator's art. This department of the school was attended by thirty-two students. Owing to the growth of local technical institutes in the Metropolis, the attendance at the art classes of the Finsbury College has fallen from 207 in 1894 to 146 last year. The diminution is mainly among students connected with the lithographic and printing trades. The classes for study of the life, enamelling and modelling still attract as many students. But

until the studios can be located in a more suitable environment than is afforded by the basement of the Cowper Street Schools, no considerable development of this department as a whole will be possible.

It was a blunder to allow the English canals to be neglected through fear of their becoming rivals to railways. There is a need of both means of communication, as the French have demonstrated. An effort is now being made to put canals into a condition that will allow them to meet more modern needs. Mr. G. D. MARTEN, the engineer to the Severn Commissioners, has been asked to report upon the Staffordshire and Worcestershire Canal, which has a waterway of about one hundred miles in length. After a thorough examination, Mr. MARTEN has recommended the following works:—(a) The widening of the bottoms of the three locks on the Severn to 19½ feet; (b) the improvement of the Staffordshire and Worcestershire Canal from Stourport to the junction of the Birmingham Canal at Aldersley, near Wolverhampton, so as to accommodate the class of vessel now required; and (c) the construction of a transshipping basin or dock at Aldersley Junction, so that goods collected at the various works lining the Birmingham Canal in Wolverhampton and the surrounding district, and brought thence down the latter canal in small boats, may there be transhipped into the large-sized vessels, which would then convey them along the improved navigation to Bristol or elsewhere. The total cost of the scheme (including the transshipping basin, the small alteration of the Severn locks, and an ample provision for all ordinary parliamentary proceedings, is estimated at 360,000*l.* One advantage of the proposed arrangement is that the works can be carried out without much disturbance of traffic. There are, however, certain works for which it would be necessary to run the water out of the canal. In the town of Kidderminster, for instance, no deepening of the canal could be put in hand until certain large buildings had been securely underpinned. Again, the canal under most of the bridges is of less width than would allow of a boat of 19 feet beam passing through, so that in addition to the rebuilding of the bridges the old masonry foundations would have to be removed. With proper organisation the whole of the works for which a stoppage of traffic would be required could be carried out in at most two periods, each commencing at the beginning of the Easter holidays and terminating at the end of the Whitsuntide holidays.

A MUSEUM of African antiquities and the art of the Mussulman has been opened in Algiers by the Governor-General. An immense number of Roman inscriptions, sarcophagi, statues and mosaics have already found a place in it. It is flattering to Frenchmen to find themselves the successors of the Romans, and the building is a tribute to their predecessors in organisation. The museum is in one of the most beautiful of the public gardens, in a position which can hardly be surpassed. The French Government have decided to have many more explorations undertaken, and the existence of the museum is also likely to inspire private collectors with a desire to enrich the galleries.

THE huge pavilion to be erected for the Diamond Jubilee Celebration by Mr. J. N. MASKELYNE in St. Paul's Churchyard, on the site now occupied by Messrs. JAMES SPENCE & Co.'s premises, has been designed by Mr. J. G. BUCKLE. The pavilion will consist of four tiers, and will seat about 2,000 persons. A distinguishing feature will be the substitution of inclined approaches to the tiers in lieu of the usual steps. The pavilion has also been designed so as to permit of the several parts being prepared away and brought upon the site ready for fixing. There will be ladies' retiring-rooms at each tier level, and refreshment saloon, lounge, smoking-room and lavatories in the basement. The cost, including decorations, will be about 4,000*l.*

## FIRECLAY MANUFACTURES.\*

YOU are all, or will be, extensive users of fireclay manufactures, more especially of sanitary pipes and specialties, glazed-bricks, scullery sinks, white channel bends, closets, &c., and I feel sure that you will be interested to know of what they are made and the process of their manufacture, which is the purpose of the present paper to describe.

First, then, let me speak of the raw material, fireclay. Fireclays abound in the coal measures of Great Britain, and particularly in the two northern counties of Northumberland and Durham. It is found most frequently as the floor or understratum of seams of coal, in layers varying in thickness from 12 inches to 5 or 6 feet. In colour it is akin to a slate grey shade. A good fireclay should have a uniform texture, a somewhat greasy feel and be free from impurities. Silica and alumina are the chief substances of which fireclay is composed. The proportions of these two substances vary very much in the clays obtained in these two counties. But I should consider a fair average to be as follows:—50 to 55 per cent. of silica and 30 to 27 per cent. of alumina. The great bulk of the clay raised is used in the manufacture of firebricks for heat-resisting purposes, but this class of manufacture I do not purpose further to refer. There is a fireclay of very fine quality and in many respects different from that of which I have just spoken. This clay is found apart altogether from the coal-measures. It is also different in colour, being of a reddish-brown tint instead of the slate grey before named. It possesses a very dense body when burned, similar to that of stoneware. The outcrop of this clay is found and worked a little to the north of Corbridge.

I will next speak of the treatment of clay. It is delivered out of the pits mostly in large hard pieces, and has to be ground into a powder of varying degrees of fineness or roughness, according to the article into which it is to be manufactured. If for heat-standing purposes, it has to be ground what we term "rough;" if for treatment for salt-glazed goods it has to be ground finer, and if for white or cane goods it has to be ground finer still, and for this latter purpose carefully selected so that no nodules of ironstone may be left in the clay, as in that case it would fuse at the great heat in burning, and spoil the goods. The modern method of grinding is as follows:—The lumps of clay are tipped into a perforated pan-mill some 8 to 9 feet in diameter. This pan revolves, and revolving within this pan are two metal rollers. The clay is carried under the rollers by the revolutions of the pan, and is thus crushed by degrees into powder, which gradually finds its way through the perforations in the bottom of the pan. Underneath the perforated bottom of this pan is a cast-iron saucer, which receives the powdered clay thus passed through the perforated mill. It is then carried round by an iron arm, so arranged that all the ground clay is forced into a well or huge pocket a little below and at one side of the foundation of the mill. Working down into this are the elevators which fill themselves with the ground clay, and carry it up to a higher storey any height that may be required, and then empty themselves into a shoot, which conveys the clay into a riddle. This riddle is hexagonal in form, say 7 or 8 feet long and 3 or 4 feet in diameter. This is kept revolving, and its action in so doing allows the fine clay to pass through the wire forming the riddle into a further shoot, which in its turn delivers the clay of the required degree of fineness to wherever it may be wanted. The wire of these riddles is of varying degrees of fineness, in some cases 15 meshes to the inch, in others only 5 meshes to the inch.

Whatever particles of clay are too large to pass through the riddle or sieve (for practically the riddle is only a large sieve) are returned to a separate shoot; that, in its turn, conveys the rejected particles of clay back to the pan-mill to be reground. The clay that has been passed through the riddle and delivered to its destination is now ready for mixing. For this purpose it is put into a pan-mill with a *solid* bottom. This pan-mill also revolves, and has within it two revolving rollers. A sufficient quantity of clay is put in, and as this is being done water is added to reduce it to a plastic condition. The metal rollers passing over this wet clay kneads, prepares and gives it body, the required stiffness being regulated by the supply of water to the clay. The men in charge of this mill can tell by experience when the clay is ready for the machine or mould. It is then taken out and ready for manufacture.

There are other methods of preparing the clay, but the foregoing is the most modern and, I believe, the most effective. In the manufacture of all the varied articles made by my firm the clay is prepared up to this stage for every one of them in the same way, rough, medium, or fine clay going through the same process, but not through the same riddle.

I have now to describe how the various goods are manufactured from the prepared clay. Firstly, I will take the process of manufacturing sanitary pipes. These are all made by a properly constructed pipe machine, which consists of

(1) a steam cylinder, (2) a clay cylinder, (3) a contrivance for forming the inside of the pipe, (4) another for forming the outside of the pipe, and (5) one for moulding the inside and the outside of the sockets. The steam cylinder stands on a metal frame placed on the strong beams or girders of the first floor. Immediately below this floor is placed the clay cylinder; between the steam and the clay cylinders is a space of about 18 inches, through which the prepared clay is thrown into the mouth of the clay cylinder by boys. Attached to the piston of the steam cylinder is a metal disc, termed a plunger, which works through into the clay cylinder and forces the clay down until it forms a pipe. At the underside of the clay cylinder an apparatus is fixed for shaping the pipe. This consists, firstly, of a cone or core, which is attached to the end of a strong rod passing down the centre of the cylinder. These cores are the exact size of the internal diameter of the pipe to be manufactured. This, you see, determines the inside size. And, secondly, a large square cast-iron plate, with a circular piece cut out of the centre, equal in size to the diameter of the outside of the pipe, regulates the thickness of the pipe. This we term the die-plate, and it is fitted on to the framework of the lower and outside portion of the clay cylinder. These die-plates correspond in every case with the size of the before-named cores, so that when the core and the die-plate are both accurately fitted into the bottom of the clay cylinder you have an open space through which the clay emerges, equal to the section of the pipe to be manufactured. But before the pipe can be manufactured, the socket of the pipe has to be formed, and, small though the socket may be in proportion to the pipe, it is much more difficult to manufacture, and takes a much higher power to press than the pipe itself, inasmuch that you have to press the thin wall of clay round a corner, so to speak, and then down the length of the socket. Separate moulds are provided, internal and external; the internal mould is a thick ring, in shape the exact reverse of the inside of the socket. This is placed directly under the core previously described, and held there until securely locked. The external mould is made in two halves, and obviously the exact reverse of the internal mould. These are worked in grooves attached to the underside of the die-plate, and are brought together by a lever. The contrivance holds all the mould, internal and external, together. When the socket-moulds are in position, steam is applied by a lever, and the clay is forced down the clay cylinder, through the space between the solid core and the circular edge of the die-plate, right into the socket-mould. When this socket-mould is filled, the two halves forming the external mould are released, the internal mould remains. Steam is applied again and the pipe is delivered to its required length, then cut off with fine wire. There is no joint whatever between the socket and the body of the pipe, the supply of clay being continuous; it is then carried away by the men to the flats to be dressed, dried and made ready for burning. Every size of pipe requires its own size of core, die-plate and socket-moulds.

Out of the pipe machines such as I have described any sized pipe 2 inches to 24 inches in diameter can be made, some fifteen or sixteen different sizes. Special machines are constructed to make pipes up to 36 inches in diameter. Pipe-machines are largely constructed in Leeds, Messrs. Pullan & Mann of that city being the best known manufacturers here. When the pipes are what we term "white" or "bone-dry" they are set in the kilns. We have found the best kind of kiln for burning pipes to be the circular kiln. These have fires all around them, so that there is every chance of the whole kiln getting equal heat. The pipes are protected from the flash of the fire by an internal wall running up 1 or 2 feet above the fire. The top of the wall all round the kiln is utilised for setting goods on to be burned, excepting the portion directly in front of the fire. These kilns are known as down-draught kilns; the heat ascends to the top of the kiln, but as there is no outlet there it is drawn by the draught of the chimney down through the pipes and through the bottom of the kiln (the arrangement of which is known as a riddle bottom) to a central well, and thence through underground flues to the chimney. When the kiln is as full as possible the door-gap is built up, the fires are lighted and the heat got up very slowly. In the course of three or four days the kiln comes to its full heat, which is so intense that looking into it at this stage you can see every part of the kiln with startling clearness.

And now comes one of the most interesting events of all the process of the manufacture of a pipe, that is, the imparting to it of the brown gloss or glaze with which you are all so familiar in a sanitary pipe. This is done by throwing into the kiln at almost its greatest stage of heat a few barrowfuls of common salt. The temperature of the kiln is so high at the "burning off" that the volatile salt is at once converted into vapour which completely surrounds all the exposed surface of pipes, &c., in the kiln, and there is consequently a reaction of the vapour on the silica of the clay bodies. The agent which promotes the action of the silica and common salt is the aqueous vapour which is always present in the flames of the furnace. The oxygen of the water produces soda with the

\* A paper read before the Northern Architectural Association by Mr. W. H. Allen on April 24.

sodium of the common salt, while the hydrogen combines with the chlorine and is evolved as hydrochloric acid. The soda then enters into combination with the silica and forms the glaze. This may be termed a coat of soda glass; or, in other words, the salt, subject to the great heat, instantly vapourises and covers every particle of exposed surface. The first application puts on to the articles in the kiln a preparatory coat of glaze, and successive charges at different periods add to the thickness and lustre of the gloss until sometimes we get what is almost equal to a coat of glass. After the last application of salt the kiln is finished as far as the burning is concerned. All air inlets are closed up and the kiln is allowed to cool down very carefully. Some idea of the time occupied in this process may be of interest to you, so I will give you a fair average of same.

Time of drying on flat . . . . .	2 days.
Time from lighting the kiln to setting it off full fire (termed soaking) . . . . .	2 "
Time under full fire . . . . .	1 day.
Time for cooling . . . . .	2 days.
Total . . . . .	7 "

This average applies more particularly to our own case; other manufacturers generally require more time, according to the nature of the clay.

Before leaving the manufacture of pipes let me say that they are made in two different thicknesses, viz. 1-10th and 1-12th of the internal diameter, the former to meet the requirements of certain engineers who regularly specify them, and the latter for general use where not otherwise specified. Bends are made from the pipe machine. Junctions are formed by sticking the size of junction required on to the pipe. Very quick bends, traps, interceptors and specialties are made from plaster moulds.

#### *Glazed Bricks.*

We will next speak of the manufacture of glazed bricks. The clay for these is prepared as previously described, then delivered to a moulder, who moulds them from a brass mould in the usual way; as soon as they are sufficiently stiffened they are pressed in a hand or steam-press, laid on the flats to dry, and when quite dry are put into the kilns and burnt to what is known as biscuit heat, or only a moderate degree of hardness; they are then brought out of the kilns again to be prepared, dipped with body and glaze and made ready for the final burning. As very few have any idea of the number of times these bricks have to be handled before they finally emerge from the kiln fit and ready for sale, I will describe the method fully. Up to this time each brick has been handled in the process thus described about ten times, and they have in the following to be handled a further ten times, so you have for a total, say, twenty times for each brick to pass through a workman's hands. The bricks are now sorted, brushed clear of all dust, and put on to a long board in patches of four or five in close contact; a boy dips a brush in water and rubs over the face or other portion to be afterwards glazed; another boy follows with a brush dipped in a certain preparation termed "tint," and brushes the bricks to fill up the pores and form a groundwork for the next process, which is the dipping of the brick in the first tint (a mixture of ball clay, &c.) of the consistency of something like cream; this is of a very tenacious and adhesive character, and completes the groundwork. It is then dipped in a mixture of about the same consistency named "body," which determines the colour of the brick; this largely consists of china clay, which gives a dead-white colour. The brick now receives its final dip in the glaze itself (a preparation of felspar, Cornish stone, &c.). But with these repeated brushings and dips there is a superfluous substance on both sides and ends of the bricks that has to be removed, or otherwise the bricks would stick together in burning, or if they did not you would have an edge that would be highly objectionable. This has to be cut patiently off every brick before it can be set in the kiln; this being done, the kiln is filled and burnt again. It takes about five or six days to burn the kiln off, and then a further week to cool it down. Quick cooling is apt to cause crazing. The whole process of glazed brick-making requires the utmost care. The proportions of the different minerals of each of the three preparations forming the tint, the body and the glaze have to be most accurately weighed out; a mistake in any one of these would be serious. The raw materials forming these are put into tanks containing water to steep, then the whole mixture has to be sieved and resieved through gradually finer sieves until a very fine liquid is obtained. Further, the consistency of this has to be regulated by weight, viz. 27, 28, 29 or 30 ounces to a pint. One of these weights will be fixed according to circumstances; half an ounce heavier or lighter will have a disastrous effect. Take the case of the glaze; if it is the slightest degree, or say half an ounce heavier than the fixed weight, the bricks may come out crazed. If it is half an ounce lighter, there will be little or no glaze on the brick.

To get coloured glazed bricks we use prepared stains to produce the required colour; some of these are applied to the body, as in blue-glazed bricks; some are applied to the glaze, as in chocolate or brown bricks.

I will next describe the manufacture of cane and white glazed kitchen and scullery sinks. These are made from moulds. After they are out of the moulds, they are squared and dressed up, and when they are required to be made white, the body determining this is brushed on with specially made brushes. It will take five or six coats of this white body to cover the clay perfectly, and give the necessary tone of whiteness, but you cannot apply more than two coats per day. The sinks must be made quite dry, or, as we term it, "bone dry" before the glaze can be applied. There are two systems in the trade for glazing sinks. One system is by twice firing or biscuiting, then glazing, as in the case of the bricks; in this case the glaze is thrown on to the sink in its biscuit stage, and then reburnt and glazed, or in some works the glaze is applied by immersing the sink in the glaze, and then burnt. The other method is by one burning only. We adopt this latter system. In this case the glaze is brushed on in a similar way to the body. Every particle of moisture has to be expelled before putting them into the kilns. Each system has its own advantages and its drawbacks, and you have to be guided by local circumstances as to which to adopt.

In the matter of kilns, sink-kilns are quite different from the well-known Newcastle or the round kiln; they are termed muffled kilns, and are constructed so that no flame may reach the contents. The heat goes all round the kiln between the outer and inner arches and gradually, but effectually, penetrates through the walls and floor of the inner arch. The utmost care has to be exercised in the burning of these kilns, first of all to apply the heat very gradually, and then to determine the exact moment when it is burnt sufficiently. Just as we are assured "There is a tide in the affairs of men which taken at the flood leads on to fortune," so there is a moment in the burning of sinks which, if seized, crowns the effort with success, or missed, ends in partial or complete failure. To enable us to attain this much desired end, small trial pieces are inserted in the kiln with the sinks, and drawn out from time to time until the crucial moment arrives, when it is declared to be finished. The kiln has then to be cooled down most carefully, which takes about six or seven days.

Channel pipes and bends, for which a great demand has arisen in late years, are made out of plaster moulds; the number of moulds required is enormous. The body and the glaze in the case of these articles can be run on; they are dried and burnt with the sinks. Fireclay water-closets, the latest development of my firm, are made in plaster moulds, accurately fitted together, the body and glaze applied as in the case of sinks and bends, and are also burnt in a similar manner to sinks. Majolica glazed bricks differ from ordinary glazed bricks in their manufacture in one or two particulars:—1. The body beneath the glaze is for the purpose of obtaining a fine surface, not so much for determining colour. 2. The glaze is very soft and runs at a much less heat. 3. There is no waste to be cut off the edges of the bricks, it overlaps without interfering with the utility of the brick. 4. Each brick has to be set face up and burnt independently of the other, and also in a muffled kiln.

#### THE FORMAL AND INFORMAL IN ARCHITECTURE.

AS the picturesque is the not unfrequent concomitant of decay or ruin, the temptation has been great among theorists on this subject to make associations of decay and ruin an element in its definition; in other words, to make the principle of the picturesque consist in the eccentric, the abnormal and the distorted, and thus by a curious inversion to discover in it a deflection from the true type of the beautiful rather than a fulfilment of it. Mr. Ruskin, for instance, finds the key to the picturesque, as may be supposed, in a theory of association, but he defines it to be "parasitical sublimity," and in explanation of his meaning gives the instance of a Swiss chalet, with the large and irregularly-shaped stones set, as usual, upon its roof, to secure it from the violence of the weather. These stones, he says, are the source of its picturesqueness, and are such, not in themselves, and as they stand on the cottage roof, but by virtue of an intellectual process in the mind of the beholder, who first associates them in thought with the adjoining mountain from which they are taken, and then mentally invests them with the sublimity attaching to that mountain. Association and romance may add poetical interest no doubt to the picturesque object, but if they may reasonably be excluded from any part in the theory of the beautiful, so also may they safely be rejected from that of picturesque beauty.

The picturesque, then, as its very name indicates, must be referred for its ultimate explanation to the art of the painter. It must be realised, that is, in one or both of the two elements of

form and colour. So much, if the principle of association be set aside, as just said, may be taken for granted. Moreover, it being impossible to have colour in a pictorial composition apart from form, whilst of course it is possible to have form without colour, as in an engraving, a photograph, or at any rate in a mere outline, we shall be simplifying our subject as well as adhering to the essential and disregarding the non-essential in setting aside the consideration of colour and confining our attention entirely to that of form. If the picturesque, then, be reducible to the general head of the beautiful in form, and if the beautiful in form be reducible, like the beautiful in colour and the beauty of motion to the head of harmony, we can hardly go astray in pronouncing the essence of the picturesque to be dependent, directly or indirectly, on what is called symmetry; inasmuch as harmony in the arrangement of lines is symmetry.

What, then, is the symmetry which distinguishes picturesque beauty from beauty in general? Here it will be convenient to recur to the illustration of the beautiful proposed by the ancient philosophers—the triangle. There are three forms of the triangle: the scalene, of which the sides are none of them equal to each other; the isosceles, of which two are equal and one is unequal; the equilateral, of which all three are equal. The scalene, then, is wholly unsymmetrical; the isosceles, imperfectly symmetrical; and the equilateral, perfectly. The scalene also is certainly not beautiful, whereas the isosceles and the equilateral both satisfy the eye, and by reason of their regularity, and though dissimilar to each other, can neither of them submit to be set aside as not beautiful. There is a difference, however, between the two, and that an important one.

The equilateral triangle, in consequence of the very perfection of the symmetrical harmony of its component parts, has the character of formality. So it is with flowers; they are beautiful, abstractedly from their colours, with a geometrical beauty, their effect, generally speaking, being produced by the systematic disposition of their petals, which are the repetition of each other round a common centre. So it is in like manner with the kaleidoscope, that instrument, by the mere power of a symmetrical multiplication, converting a chaos of disorder into magical beauty—still into beauty of a limited range only, as being by the necessity of the case always formal. The isosceles triangle, on the other hand, is saved from being formal at the expense of being less completely symmetrical, and its third side, which is irregular or unsymmetrical, as compared with the other two, is of the nature of a discord in music, as employed by a great master. It tempers a harmony which would otherwise be too perfect to be quite symmetrical.

Here, then, we get a glimpse of the true reply to the question above put, viz. What is the symmetry which distinguishes picturesque beauty from ordinary beauty? for the most cursory consideration of all that is generally included under the name picturesque, will lead us to see that its chief characteristic is a certain irregularity: formal it assuredly is not, whatever else it is. We may accordingly distribute all beauty into formal on the one hand, and picturesque on the other. And, speaking broadly and generally, we have the types of these two divisions of the beautiful in the two triangles just mentioned, viz. of the formal in the equilateral, and of the informal or picturesque in the isosceles.

For the more complete illustration of the distinction here drawn, let us now place ourselves in imagination in the presence of any particular masterpiece we please of Classical architecture, only supposing it to be as perfect as on the day when it was originally set up by Pericles at Athens or by Augustus at Rome. It may be the front of the Parthenon, or the portico of the Pantheon, or the Maison Carrée of Nîmes, or that imitation of the antique, the Madeleine at Paris. Anyhow we shall have before us a range of columns, Doric, Ionic, or Corinthian, as the case may be—perfect in their parts, their heights, their proportions, their inter-columniations. Above these the horizontal entablature, adorned with its appropriate decorations according to the style of the architecture; and above this again, and crowning the whole, the pediment, with its obtuse-angled triangle, forming at once the termination of the roof of the temple and the frame of a series of exquisite representations in sculpture arranged within it. Now, such a creation as this is emphatically and by universal consent beautiful—as beautiful in its particular department as anything that can be named; yet assuredly it is no subject for the painter. He might do his best, indeed, were he compelled to design it, in the way of adapting it to a picture, whether by taking it at an angle, or by setting it on the summit of some rugged and commanding rock, as the Parthenon on the Acropolis; or by relieving it with the undulating lines of trees and clouds; or by breaking up its uniformity in casting upon it broad lights and irregular shadows; but were he to draw the front of the building as we have described it, and, apart from such accessories or details as we have just been imagining, he would produce, not a picture, but an architectural elevation. The result, in fact, though perfectly beautiful in its own way, would

be irremediably formal; and where is the spell that shall evoke a manifestation of the picturesque from materials so unpromising?

In Sir Walter Scott's "Bridal of Triermain" we read of a knight who, weary of continually watching before a pile of rocks, which remained nothing but rocks, though a magical castle was said to be concealed within them, at length flung his battle-axe at the cliffs which rose above him, and splintered off a fragment of the mass in so doing, when, the charm being thus broken, the enchanted fortress immediately burst upon his view in all its reality. Now we may try a somewhat similar experiment in the present instance with equal success. For the castle rocks of St. John, which Sir Roland struck, let us substitute the façade of the Classic temple just imagined, and let the blow of the battle-axe be represented by some partial disturbance of the severe regularity of the outlines which bound the structure; let the pediment be somewhat broken away; let one or two of the pillars be displaced or broken off short at different elevations; let the continuity of their fluting be disturbed, let them be eaten into by the weather, and overhung and tufted in places with creepers or wild flowers; let the monotony of their marble be diversified with moss and lichen; and let the ground at their foot be broken and heaped up in hillocks, and behold a nobler creation of the beautiful than we had before—*dum moritur resurgit*—from the prison of the formal has come out the beauty of the informal, for in the ruin we have the subject of the pencil, the delight of the artist, the material for the sketch-book, in short, the very embodiment of the picturesque in all its perfection.

We repeat that we have here given what every one must admit to be a specimen of the picturesque, true, adequate and complete, *omnibus numeris*, and the principle of the picturesque may now be easily deduced from the consideration of it. It is, in fact, a disturbed symmetry, and where it is realised most completely will be found to be a pretty accurate equilibrium of the symmetrical and the unsymmetrical, neither absolutely preponderating to the disadvantage of the other. Hence, while the modes in which it admits of being exhibited are very various, the essence of every such exhibition will be always this, all that is possible in regularity short of formal arrangement, and all that is possible in freedom short of no arrangement at all or mere disorder. There must be an interpenetration, so to express it, of the formal by the informal; there must be at once correspondence and diversity, harmony and contrast. This, and this only, is the picturesque; and of this the isosceles triangle, as before said, is the simplest manifestation.

Should anyone yet hesitate to acquiesce in this definition, under the feeling that after all it may be still association which is the charm of the ruin, and not the form of it, let him return again to the supposed temple and consider what would be the effect of an entire abolition of those proportions which he is so little disposed to identify with its picturesqueness. That in its formal or complete state the piece of architecture in question is unpicturesque has been made evident already; now, on the other hand, that an utter absence of form or simple disorder and confusion is unpicturesque also, may be proved to demonstration by pursuing to its limits that same process of demolition by means of which we rendered the temple picturesque in the first instance. Carry on, in fact, the supposed disintegration of the building little by little, and you will find that at a certain stage of the proceeding you reach a critical turning-point, beyond which every step in advance ceases to be a creation of the picturesque, and becomes the corruption of it; till at length, when column, pediment and entablature lie in shapeless confusion on the ground, corruption has become absolute dissolution, and the picturesque has vanished. It has come, it has been seen in its perfection, it has passed away and has been destroyed by the identical process by which it has been erected; as if the conditions of its existence were those of the White Lady in the romance, who then first became visible when the fortunes of the "house of Avenel," with whose destiny her own was interwoven, had fallen into decline; whose zone gradually dwindled as the ruin proceeded, and who was fated to perish altogether at the moment of its consummation.

The picturesque then is, in its essence, a due combination of the formal and the informal, and it is important to observe that this is the definition, the most natural and antecedently probable in a philosophical point of view, of any which could be given; for the discernment of likeness and unlikeness, which are only other names for that system of symmetry and interruption, of correspondence and contrast, which we recognise in the picturesque, is an elementary power and necessity in the human mind: hence it is a principle of universal application; *latissime patet*. "The perception," it has been said by Wordsworth in his preface, "of similitude in dissimilitude is the great spring of the activity of our minds and their chief feeder. . . . It is the life of our ordinary conversation, and upon the accuracy with which similitude in dissimilitude and dissimilitude in similitude are perceived, depend our taste and our moral feelings." Thus it is the secret, for example,

as others have pointed out, of the reason why we prefer the marble statue to the more perfect imitation of the human form which may be made in waxwork. Thus in poetry, again, it is the ultimate principle of the entire scheme of metre, versification and rhyme, and of the system of parallelisms which constitutes the versification of the Hebrews; of metre, for it is here the similitude and dissimilitude of time or measure; of rhyme, for it is here the similitude and dissimilitude of recurring sound; of parallelism, for it is here the similitude and dissimilitude of mental conceptions. It is the main principle, in short, of the charm residing in all imitation of whatever kind.

This law, then, of our condition, that we should be incessantly comparing and contrasting, contrasting and comparing, and finding pleasure in the recognition of the like in the midst of the unlike, being identical, in fact, with the law which constitutes the picturesque, we may naturally expect a principle so universal to admit, even in the particular province of the picturesque, of extensive application; and, in truth, it is hardly too much to say that according to the variety of the employment of it is the success, the beauty and the perfection, so far as form is concerned, of a pictorial composition. Thus, an object may be picturesque, for example, in itself, according to the definition of the picturesque above given; or, on the other hand, it may be picturesque only or mainly when in juxtaposition with a second object, partly resembling the first and partly differing; it being just this union of resemblance and difference which constitutes the picturesque. Or, again, each of the two objects may be properly picturesque in itself, or taken separately, and the two may also create the picturesque when taken conjointly. An oak, for example, if well grown, is a picturesque tree. Its stem is just a sufficient departure from a straight line to save it from being formal, and its foliage groups into masses corresponding one to another in character, yet not rigorously uniform—repeating one another with variations and perpetually suggesting a symmetry which they stop short of completing. If a tree, then, such as this, be introduced into a picture alongside of a piece of architectural ruin of the kind before mentioned, the one, to use the common expression, will set off the other in a manner and to a degree in which neither one tree would set off another tree, nor one ruin another ruin; or, in other words, owing to the character of their outlines, there will be at once a certain difference in the opposed masses and a certain correspondence, and the picturesque will be the result.

It would be easy to continue these illustrations almost indefinitely. What, for example, is the secret of that picturesqueness of the Swiss chalet which Mr. Ruskin mistakenly attributes to "parasitical sublimity"? It is simply that the rough masses of irregular stone with which the roof is studded interrupt what would otherwise be the over-formality and regularity of the lines of the building. Why is it, again, that the painter, who has a picturesque object to copy, avoids giving it a place in the exact centre of his paper? It is the fear lest, by consequently dividing his paper into equal parts he should give an air of formality to his drawing, which would destroy its picturesqueness. Or, again, what makes him prefer taking his building, be it castle or cottage, at an angle, in preference to a front view of it? It is obviously the feeling that the slanting lines thus produced by the necessity of the perspective tend to mitigate that decided formality which would be the consequence of a front view. Or, again, why is he so fond of balancing the two sides of his picture? Why will he put a small tree on the left hand over against a large one on the right, a large rock on the right to balance a small one on the left, unless always with the intention of producing a certain correspondence without formality? In the case of a historical picture, as distinct from landscape, the introduction of the same principle of arrangement is more remarkable still, for there, if anywhere, the dignity or the interest attaching to the exhibition of human action or passion, to expression in countenance and feature, and to animation in form, might seem enough in itself for the highest purposes of the artist, without the addition of the particular element we are here treating of. Yet it presents itself, in fact, in what are called the "forms of composition" employed by the great masters. In other words, some regular figure, whether the triangle, the circle, the oval, the figure of eight, the St. Andrew's cross, or any other, is made the basis of the composition or grouping of the different personages which are the subject of the picture; not, however, in such a manner that the employment of the figure in question becomes prominently conspicuous; but here is again that peculiar intermingling of the formal and the informal which constitutes the picturesque. The severe regularity of the figure is just so far discernible as to give harmony and repose to the irregular life and action out of which it is created, and is so far indiscernible as only to regulate a freedom which it would otherwise imprison.

(To be continued.)

Mr. C. W. Smith, Market Place, Grantham, is the successful architect in the Nuneaton Warwickshire Conservative Club Competition.

## NEW CUNEIFORM TEXTS.

THE records of Bible archæology have during the last few years been largely increased, says a correspondent of the *Glasgow Herald*, by the discoveries made among the ruined cities of Assyria and Babylonia. Their treasures seem inexhaustible, and one can only long for the time when the heavy hands of Turkey will be lifted from them and the spade of the explorer permitted free play. One of our most accomplished Assyriologists, Mr. Theo. G. Pinches, of the British Museum, has been working out from the cuneiform texts the details of the times of Chedorlaomer and his allies who are referred to in Genesis, chap. xiv. The invasion of Palestine recorded there was only one of the episodes suggested by the annals, which are now known to be admirably illustrated by it. For this reason—along with others—Mr. Pinches deserves the thanks of all interested in such researches for his laborious and painstaking services, which in this case have turned out so successful. He is now having a paper printed giving full particulars, which tend well to lighten up the early history of our race, so that one may well say with him, "the dark places of history are indeed disappearing."

One point is put beyond doubt by these texts—the personages mentioned in Genesis xiv. as invading Palestine turn out to have been historical, though this was disputed a few years ago—and not only so, but they are described as a compact group, such as are recorded in the history of Abraham. This was recognised several years ago when Professor Sayce was led to assert in 1892:—"So far as the historical arguments are concerned, the cuneiform inscriptions show that it is the critic and not the Book of Genesis that has been at fault."

Since that time new texts have been found, confirming the previous readings and enlarging our information of these times. To Father Scheil—perhaps the most successful discoverer of such monuments of late years—we are indebted for the knowledge of three tablets now in the Museum, Constantinople, with most important texts, which well elucidate the history of such far away times. These chiefly induced Mr. Pinches to enter again on the investigation of the story and form the basis of his expected paper. How far back the times were we can form some idea from the following considerations, apart from our Bible. Assurbanipal, the warlike son and heir of the Bible Esarhaddon, whose library is now secured in the British Museum, records in his annals that in his eighth campaign, 659 B.C., he recovered the image of the goddess Nana, which the King of Elam, or Kudur Nanchundi, had carried off from "the land of Accad," or Babylonia, 1635 years previously, and restored it to Erech, her native city. This leads us back to 2294 B.C., at which time we are told by Berossos the Medes had conquered Babylon and established a dynasty of Elamite princes, instead of a native Government. One of these was named Kudur Mabug, whose inscriptions found at Ur tell us that he reigned as far as Syria.

His son Eriaku names himself "King of Larsa (Ellasar of Gen. xiv.), Sumer and Akkad"—i.e. of the entire country—so that Kudur Mabug was his father and his suzerain prince at the same time. This Eriaku is for such reasons taken to be the Arioch of Ellasar of Genesis, and the name of Chedorlaomer appearing in the texts of this time as an Elamite prince, there was less difficulty in admitting their identification. Tidal and Amraphel have also been found in them, and all that remains is to work out the details of the inscriptions, so that we may for ourselves find out "the form and fashion of the times" when they lived. This is what Mr. Pinches and others are doing, leaving their translations to speak for themselves. Accordingly, such texts written by Babylonians describe Chedorlaomer as "the enemy," the "evil man," who burst into Babylonia "like the god of war" harrying the temples all over the country, and who did not refrain from the most sacred shrines of the capital—E. Sagila and E. Zida—the temple of "the seven lights of the universe" itself. These are said to have been destroyed, but allowance must be made for the highly-figurative language of Orientals, especially when we know that Herodotus found the temple existing in his days, and that the mountain ruins of Birs Nimrod represent it in our own times. For 4,500 years have these basement-bricks remained *in situ*, and on this ground, at all events, may represent the identical bricks made by the early inhabitants of the plain of Shinar for their tower to reach to heaven—the tower of Babel. So thorough was the work of destruction carried out that mention is made of waters overflowing the city and temple of Sagila, and other passages speak of the city and the entire land of Kar Dunias as being given over to destruction.

Ine Tutu, the Patesi or governor of the city, fled in terror to the marshes of Chaldea, where he remained till the storm was over. We are then told that the conqueror withdrew and passed to the north—to Shishkish or Sheshach, as Professor Sayce reads the word.

Babylon and the entire holy land of Kar Dunias was thus prostrated before Chedorlaomer and his warlike hordes from Elam—the Umman Manda as they are called in the text. But,

like many conquerors since, he found it was one thing to subdue a people and another to secure their confidence. A new text in the form of a letter sent by Hammurabi—the most powerful of the native princes—to one Sinidinnam, the Babylonian King of Larsa, has been found, in which he promised as a gift the present of a celebrated image as a reward for his bravery in resisting Chedorlaomer. This letter is very significant, as it tells us how important Hammurabi then was among the native rulers of the day, as well as how sorely pressed they were by the Elamites. That this inference is justified we learn from further texts, which show how Hammurabi became the leader of a native confederacy who drove the Elamites from the country, and became the first monarch of a new dynasty of native princes. Many points are raised by these new texts which cannot be considered here. That this Elamite invasion made a profound impression on the whole future history of Babylonia seems clear. It is suggested in the national epic of Gilgames or Izdubar, where he and Hëabani went to free the beleaguered city of Erech from the Elamite tyrant Humbaba, an epic in which are embedded many primeval traditions. To mention only one here, we read that the two heroes, in their pursuit of the tyrant, enter a holy grove, where was the cedar-hill, the dwelling-place of the gods. Here is a magnificent garden (a paradise), in which a cedar (the tree of life) is distinguished from other trees as peculiarly beautiful. This was in the neighbourhood of Kardunias, the holy land of Babylonia, in which F. Delitsch found reminiscences of the Bible Eden, and from which in all likelihood arose the mystical name of the capital Tin-tir-ki, itself the “seat of life”—*subat balati*.

But the terror it produced could never be effaced. How ferocious the tyrants were is shown by these texts. We read that Chedorlaomer “his son with the iron dagger of his girdle pierced his heart,” i.e. of his father, whose name unfortunately is wanting. Dur-sir-ilani, son of Arioch, is suggested as slaughtering some person “like a lamb” in words that speak of a son doing so, and immediately after Tidal “fell on his father with the weapon of his hands, and then proclaimed his sovereignty before the temple of Anunit.” Can we help agreeing with Pinches that these three contemporaries were parricides, and that they were impelled to the invasion of Babylonia and Palestine by personal ambition? If so, the resistance and check to their ruthless career inflicted by Abraham under God was a blessing to the race.

#### EDINBURGH ARCHITECTURAL ASSOCIATION.

AN ordinary meeting of the Edinburgh Architectural Association was held on the 21st inst. in the Royal Institution, Dr. R. Rowand Anderson, president, in the chair. A large number of drawings of old Scottish work, by students of the Applied Art School, were exhibited, and explanatory historical and architectural notes on them were read by Mr. J. Forbes Smith and Mr. Ramsay Traquair, students. Among the subjects of the drawings were Holyrood Abbey, Craigmillar Castle, Argyll's Lodging at Stirling and Cowane's Hospital.

The Chairman, in proposing a vote of thanks to Messrs. Ramsay Traquair and Smith for their communications on the interesting buildings they had been studying, said that the Association, in devoting one of its evenings to an exhibition of the work of the students of the Applied Art School, was desirous to make it known, especially to the young men who were to follow applied art, that the Association was doing its best for them, because it made annually a handsome subscription from its limited means to forward the cause of education, and it desired to make it known that it did not limit its subscription to benefiting those only who were to follow architecture, but that it gave its support to a school which, in carrying out its system of education, made no distinction between the architect and all other art-workers—that was to say, that the scholarships and other rewards at the disposal of the school could be obtained and held by the decorator, the sculptor, and any other art worker equally with the architect. The Association also desired to emphasise the great importance of the study of ancient work, in all its departments, as a true foundation for the future work of the artist. Work of the character they saw that night might be described as analogous to anatomy in the study of medicine. They brought the student into actual contact with work of all kinds. He was taught to dissect, to analyse, and to work out for himself all the reasons that gave rise to the various features he saw in buildings. All artists of eminence had recognised that the study and analysis of ancient work were among the most important factors in the education of all art workers, and the Association desired to make it known as widely as possible that the Applied Art School held out every inducement to students within its, he was sorry to say, somewhat limited means, to come and perfect their education.

The Association visited on the 24th Bavelaw Castle, near Balerno, by permission of Mr. Charles Gulland, commissioner for Mr. George Johnston, of Bavelaw, and Mr. Robertson, the

tenant. Mr. Frank W. Simon, architect, who led the party, described the castle, and Mr. Glover, factor for the property, supplemented Mr. Simon's description. On the motion of Dr. Rowand Anderson a vote of thanks was given to Mr. Gulland and Mr. Robertson, and to Mr. Simon for his descriptive notes.

#### THE PARTHENON.

THE following letter by Mr. J. R. S. Sterrett has been sent from Athens to the *Evening Post* of New York:—

Perhaps many who have seen the stately pile only from below will be inclined to doubt statements brusquely made. Indeed, when one sees the ruin from a distance, or looks upon it from among the pillars of the western façade, it seems so strongly built, so secure, that the visitor has no thought of decay or ruin, but leaves the place under the impression that the Parthenon will continue to defy time for thousands of years to come. But the fact is that, ever since the last earthquakes, its immediate ruin has been a foregone conclusion in case another earthquake should occur before certain contemplated repairs shall have been completed. At this moment the whole western façade is disfigured by an immense scaffolding, built in the strongest possible manner from enormous beams that were brought all the way from America to succour Athene. This mighty scaffolding subserves a twofold purpose: primarily it enables the architects to replace certain rotten and broken architrave blocks with fresh blocks, but its important secondary purpose is to serve as a prop to the entire entablature, and prevent the collapse of the building in case an earthquake shock should visit Athens, an event that may occur here at any time.

Visitors are excluded from the scaffolding, but I gained admittance on two occasions recently, and was thus enabled to examine at close quarters the frieze of the western end. From the base of the columns below any study of it is out of the question, firstly because, owing to the projecting epistyle, the bottom of the frieze cannot be seen; then again because the whole frieze is distorted by the sharp perspective and the lower-lying parts of the reliefs are obscured by the higher. The scaffolding thus affords a unique opportunity for the study of certain chapters of Phidian art.

But, not to dwell longer upon the frieze in this connection, I was dismayed at what I saw. The inside and interior stones of the entablature, colossal though they be, are rotten through and through; in some cases these rotten stones were broken by the recent earthquakes into many pieces, though, by the veriest miracle, the pieces still cling together. As is well known, the epistyle consists of three huge blocks that stand on their edges side by side and span the intercolumniations. Of these three blocks the outside ones alone are comparatively sound, while the interior and inside blocks are in a most ruinous condition. All of these inside blocks are to be replaced by new ones that are now lying on the ground below, ready to be put into position as soon as the mighty derrick that is to lift them on high shall have arrived. The new blocks will be coloured with oil and wax in order to rob them of their glaring whiteness and newness. Even more sorrowful is the fact that, though this ruin may be stayed for one or two centuries yet to come, still in the end the Parthenon must collapse unless virtually the whole entablature be replaced by new and sound stones.

For this ruinous condition of the Parthenon several causes have been in effective operation for many years, though unsuspected. In point of fact the builders of the Parthenon employed first-class marble only on the outside of the building, only where the eye could see it. In the Pentelic marble there are veins of schist that disfigure and ruin many a fair block. Visitors will remember the many unfired drums of columns that lie here and there around the temple. These are drums that were rejected by the builders—rejected because they were faulty in some way, often precisely because of this disastrous vein of schist. Indeed, one of the new epistyle blocks has just been rejected by the committee of architects because of its faulty character, which was discovered only after the block had been completely hewn and was ready to be hoisted into position. Of course perfectly sound marble was employed in the columns, both because they were completely visible and also because they had a great weight to carry. Sound marble was employed also for the outside blocks of the entablature and in the outside stones of the cella wall, but the inside stones and the completely hidden interior stones of the epistyle and cella walls were faulty from the start—faulty because of this vein of schist.

As long as the building was covered by a roof the faulty character of these stones was of no importance whatever, and as is well known, the Parthenon was always covered by a roof until its final disruption by the gunpowder explosion two centuries ago. The ruin that now threatens the portion of the Parthenon left standing on that fatal occasion began from the moment of the explosion, and it has become more

threatening with each succeeding year. The roofless condition of the building has made it possible for the rain to penetrate into the schist veins of the faulty stones, and the frost of winter and the scorching sun of summer made the evil greater from year to year, until at last we discover that these stones are rotten throughout, and that utter ruin is impending.

And here comes in a fear for the frieze, the glorious frieze, that fairly palpitates with the genius of Phidias. When the final collapse of the Parthenon comes, the frieze will be gone for ever. This remote danger, however, is not the only one that threatens the frieze, for there it stands, exposed, like all the building, to slow but certain decay and ruin. In the recent earthquakes the head of one of the horsemen was broken off and dashed to pieces on the marble floor below. A similar fate is in store for the entire frieze, for the rotting is already visible in the reliefs. These reliefs ought to be removed now, so that they may be preserved in the museum for ages after the original entablature has ceased to exist. Dörfeld did, indeed, propose to the committee that the frieze be removed to a safer and drier place, and be replaced by a marble copy. But conservatism carried the day. The thought, too, that the removal of the frieze to the museum would seem to justify the spoliation of the shrine by the deeply detested Lord Elgin had much to do with the stand taken by the majority of the committee. The frieze, therefore, will remain *in situ*, and will perish. There can be no doubt that the Parthenon would hold out for many centuries longer if it were covered by a roof. The care which the Greek Archæological Society bestows upon all the ruins is worthy of unstinted praise. The ruins are now placed behind strong iron bars. A great iron fence protects the whole country between the Odeion of Herodes Atticus and the Theatre of Dionysos. Another fence protects the Dipylon Kerameikos region, another the Areiopagos and the sanctuary of the Eumenides, once the rendezvous of gipsies and unsavoury tramps. Nor is this change for the better seen and felt in outdoor matters only; the museums themselves are now arranged and managed in a most satisfactory manner. Something like order reigns, and scholars may study without vexation and loss of time.

### TELEGRAPH POSTS IN THE COUNTRY.

IN a letter to the *Times*, Mr. W. C. Renshaw, of Hayward's Heath, writes:—It seems to me that the time has come for calling attention to the methods of the post office in connection with the erection of telegraph or telephone lines. Here in Mid-Sussex one of our main roads—namely, that leading from North Chapel *via* Lindfield to Brighton—has lately been made available, not for any purposes relating to local service, but in order to facilitate direct telephonic communication between London and Brighton exclusively. This work is being executed on a large scale. The posts, some 30 feet high, are fully a foot in diameter and are maintained in some cases by converging wooden props inserted in the ground about 2 feet or 3 feet from the main post, and in others by metal stays set at varying distances, but in either case making a sort of trap.

The general results are a hideous disfigurement of a hitherto pretty country, and an addition of danger in case of a runaway horse or a bicycle running downhill out of control, which, having regard to what I call the traps, makes one shudder to contemplate. The particular results are a great diminution in the frontage value of land and permanent obstruction to the opening of new gateways or roadways into the high road without any compensation to the person aggrieved.

But all this when the road authorities, with more or less indifference, give their assent, appears to be legalised by the Telegraph Act, 1863, into which for "company" must under the Act of 1868 be read "Postmaster-General." Now what I complain of is that, in carrying into execution the wide powers conferred upon the Postmaster-General by them and the other Acts, no regard is paid by his officials to the provisions contained in them for the protection of landowners and others.

Section 21 of the Act of 1863 imposes a prohibition against placing any "work" in any land without the previous consent of the owner, &c. By section 3 "work" includes "telegraphs and posts," and post is defined as meaning pole, standard, stay and strut. This is sufficiently plain, but the officials do not hesitate to injure the hedges, to dig into the banks of the owners adjoining the road, and therein to affix metal stays or wooden struts fastened into buried pieces of wood about 4 feet long without even asking for consent. I myself wrote to the Secretary of the Post Office on January 31 complaining of trespasses of this description, and on February 2 received an acknowledgment stating that my letter should receive attention. It has received such prolonged attention that I have never had an answer yet. This very morning workmen were engaged digging a large hole in one of my hedge-banks, which the foreman frankly admitted was my property, but said he was

under orders to do it. If an individual did this sort of thing on his neighbour's land I think his conduct would be stigmatised by some strong epithets.

Section 12 of the Act of 1863 enacts that when a public road passes by the side of any park or pleasure-grounds, or crosses or abuts on a private drive to any mansion, the company (*i.e.* the Postmaster-General) shall not without, or otherwise than in accordance with, the consent of the owner, &c., place any "work" above ground on such public road. In 1892 a telegraph line on posts was laid along the public road called the Rookery Lane, abutting for some third of a mile or more on my pleasure-grounds, and a post was set up immediately opposite my entrance gates and ornamental trees were mutilated to make space for the wire. No consent to place this work above ground was asked for. In this case also trespasses by posts and stays being inserted in my land were committed.

The Acts contain, so far as I can find, nothing which authorises the cutting or mutilating of trees, whether ornamental in the legal sense or not. As to this I am bound to add that my permission was lately asked by an official to cut some old Scotch firs, whose object is to hide out a row of ugly cottages, but it was only asked for after the posts had already been erected in such a position that the wires could not be put up without mutilating the trees, and this notwithstanding that there was already a line of posts carrying only two wires on the opposite side of the roadway.

### TESSERÆ.

#### [The Arts and Literature.]

THERE is a pathological connection between the arts, the drama and the complexion of natural literature more or less marked in the evolutions of history. As the geologist from the plant vestiges in the earth's crust can construct the animals at any period on its surface, so from the sculpture and frescoes of the Roman empire we can set up the habits of life, the degree of refinement, the nature of the literature—nay, the very reign under which they sprang into being. The whiskered busts of Hadrian point as indisputably to the rhapsodies of Valerius Flaccus and Statius as the chaste marbles of Augustus to the productions of Horace and Virgil. The culture of the beautiful reached its highest development in the age of Pericles, and with it was associated the most brilliant literature and the profoundest dramatic art the world has yet seen. As art declined with the waning power of the Roman empire, literature and all relish for pastimes of a purely intellectual nature fell along with it. If the reign of Constantine signalled the triumph of the Christian Church, it was upon the ruins of the literature and artistic creations of the Roman world. For a thousand years statuary and painting lay buried beneath the soil of Rome and Greece, and in the same grave lay two literatures whose greatest achievements were contemporaneous with that of the two arts which they had followed to the tomb. The peculiar dogmas of the Arabs were hostile to sculpture and painting, and when their empire culminated under the Abassides, their warlike spirit gave way to scientific researches. But there was no art, and consequently no literature having the slightest claim to originality. It will not, therefore, startle us to find that when those arts sprang into new life under the Medici, a powerful literature was seen side by side impressing its influence upon Europe. With ourselves, the perception of the beautiful, in so far as its realisation was felt in our daily life, was most manifest during the era of Elizabeth, and contemporaneous with that spirit our national drama then achieved its proudest distinction. But for these revivals, the exhuming of Greek statuary from the Italian soil prepared the way quite as much as the dispersion of Greek manuscripts from the shrines of Constantinople. The recovery of a Greek Antinous or Erato had the same effect in rescuing men's minds from the gloom of barbarism as the detection of the works of Euripides in some old palimpsest out of the convents of the Hellespont. The literature was quickly rivalled, and in some respects surpassed. The sculpture still remains to reproach us with our littleness, and urge us to loftier flights in the sphere of ideal creation.

#### Canute's Canal.

Canute, king of Denmark, when he besieged London, was impeded in his operations by a bridge, which, even at that time, must have been strongly fortified, as it obliged him to have recourse to the following expedient. He caused a prodigious ditch to be cut on the south side of the Thames, commencing at Rotherhithe, and which he continued at a distance from the south end of the bridge in the form of a semicircle, opening again into the western part of the river. Through this he drew his ships, and effectually completed the blockade of the city. Evidences of this great work were found at Dock Head, at the end of Tooley Street, where it was first commenced.

Fascines of hazels and other brushwood, fastened down with stakes, were discovered in digging the dock in 1694; large oaken planks and numbers of piles have also been discovered in other parts of its course. It is, however, doubtful whether what was found was evidence of a canal rather than of submerged vegetation. In 1826-27 an excavation was made the whole length of Bermondsey Street into Tooley Street for the purpose of building a new sewer. The first few feet were made ground, merely rubbish; then came a thick, close sedimentary deposit of alluvial clay and Thames river mud, averaging about 7 to 10 feet thick, which evidently had its origin in the tidal and sedimentary matter from the adjacent river; below this mud and clayey deposit was a close stratum of peat, tightly compressed, varying materially in thickness in different places along the street, but averaging from 2 feet to 4 feet and 5 feet in thickness. This peat was chiefly composed of vestiges of hazel-trees, hazel-nuts (in beautiful preservation), fragments of oak, beech and other trees, and leaves and stems of various plants confusedly intermixed, the wood and hazel-nuts and the oak differing in no respect in their character from what might be grown at the present time in the same county. This peat and wood had undergone no apparent chemical change; it was highly saturated with moisture, had rather an agreeable odour, of a light brown colour, and fragments of the hazel and oak wood on being kept in a dry situation for two or three months shrunk into about one-tenth of their original size by the evaporation of the combined water, but left the outside bark in its original shape, while the remaining inside ligneous fibre of the hazel or oak became (on cutting it with a knife) nearly as black and as hard as ebony. Below this stratum of peat came the usual angular fragments, called by geologists diluvial gravel, consisting of fragments of flint reposing on the great argillaceous deposit of the blue London clay. A continuous formation of the peat stratum and the alluvial mud and clay reposing on it can be traced along the banks of the Thames at Limehouse and at the entrance of the London Docks, as well as at the East India Docks, Blackwall, and in that neighbourhood. From the above statement of facts one or two interesting inferences or deductions may be drawn. First, that at the time when the above hazel trees and wood were growing (at the depth now of 10 or 12 feet), the relative level of the height of the water in the Thames must have been at least 12 feet lower than it is at present. Secondly, it is highly probable that, even long anterior to the time of the Romans, this forest or wood must have become submerged by the vast accumulation of the Thames sedimentary mud and clay, thereby accounting for the progressive rise in the relative level of the river to that which we at present witness at high water.

#### Sir W. Chambers.

Sir William Chambers threw no new lights on the art over which he was destined to preside. In its practice and more scientific department of construction he was, comparatively with such men as Wren and Hawksmoor, totally ignorant. His taste was Roman, and, being unacquainted with the sublimer beauties of Grecian art, was consequently less refined; yet his works have a chastened correctness of detail of the best style of Italian art. He is less exuberant than Scamozzi, Serlio and Borromini, and even than Palladio himself, except in his very best examples. He may be called the *Palladio riformato* of the Georgian era. In the course of his travels he had visited parts of China, and published a treatise on the gardening and architecture of that strange people. The royal gardens of Kew and its lofty pagoda are among the results of the Chinese phantasy that he had inflicted on his royal master, and led to the introduction of that fanciful and inelegant style. Yet the Somerset House of this architect has many redeeming beauties, and his work on "Civil Architecture," in spite of bad taste in reviling the architecture of ancient Greece, of which he knew nothing, abounds with sound doctrines. Fond of ease, he indulged in his professional reveries in his office at the Board of Works. Not being a regularly bred architect, or even builder, he educated no pupils—that is to say, as the word is now understood; he therefore formed no school, and left little more than his Somerset House, a few edifices of lesser notoriety, his Chinese buildings at Kew, and his "Treatise on Civil Architecture" to perpetuate his fame; but his name will always hold a distinguished place in the list of British architects. His only followers or pupils were bred in the office of the Board of Works, in which he held the situation of surveyor-general.

#### Ancient Seals.

Whenever we find an old charter or deed with a seal in tolerable preservation we have another link added to the chain of historic evidence—it establishes original relations between public or private parties—it elucidates the records of heraldry, it shows the state of art as it then was, and in other ways it serves to fill many a gap in local or even general chronicles because of the precision in the ancient method of seals, whereas

now, how is it? Who would think it worth while noticing the mass of devices, or care to add them to a collection? They tell no tale and imply no meaning. Except in the most solemn instances we have nothing but disorder in their use; the seals of one office confounded with another; privy seals and public seals impressed at random; one person borrowing his neighbour's, and his neighbour's answering for all the world, if the world please; individual officers adopting devices mistaken afterwards for the stamp of the office itself, or perhaps for the coat-of-arms of a county or city or corporation, instead of the person's representing it; and even, when regularity is aimed at, designs formed upon no clear principle, heraldry mixed with allegory, fancy preferred to reason, or ancient symbols set aside for individual whim. In short, seals have long altogether lost their import. The Normans required the seal in addition to the signature, a point not essential with the Saxons, though occasionally used by them. But then the Mediæval noble stuck his own tooth into the wax, "In witness of this sooth," "I seal with my fang tooth;" or he put a bit of his own hair into it in token of his personal bequest, or left the impress of his own fingers deep on the back of the wax when he placed them on it, saying, "My act and deed," or plucked some of the grass itself as a first-fruit of the land which he conveyed, and so identified it with the substance of the seal, or endorsed it with his own signet, or badge or other mark which could be mistaken for no one else's but his own, or even fastened a ring, or knife or pledge of some kind to the deed. So particular, indeed, were they (even from the classical era) that the seal was examined critically, and in after times, when every landowner used his seal, a facsimile of most of the important ones was laid up with the registrars, often impressed on lead, in order to detect forgeries.

#### Æsthetics and Art.

This being a critical, conscious age its artists must be critical to fulfil its demands, and æsthetics we take to be one of the means of elevating it out of the "slough of despond;" although it must likewise be emancipated from "commerce," and be placed on its own high pedestal, with real priests at its altars and real faith in its worshippers; so long as the "commerce of sweet sounds" is the jingling of guineas, little can be hoped for. But that æsthetics, however studied, is able to create artists we do not for an instant imagine; it can but direct the artistic genius. Æsthetics is the philosophy of art, and "philosophy," says Solger, "can create nothing; it can only understand. It can neither create the religious inspiration nor the artistic genius, but it can detect and bring to light all that is contained therein." To create a new and commensurate art is not in the power of æsthetics; that must come from the new birth of an era; there must be the inspiring ideas, but as in all the secondary stages men are employed in developing the many phases of the idea, æsthetics, when perfected, will necessarily direct their energies into the right channels. And this leads us to the indisputable position of æsthetics. If it be of no assistance to the artist (which we deny), it will render intelligible art as art, as well as all existing works; it will enable us fitly to judge of the relics of the past and the productions of the present, and it opens an inquiry in the psychological department of the very highest interest. For these, then, do we demand a consideration of the subject. In France, although rapid strides have been taken and some notable results elicited, it still remains in a fragmentary state. The works of Quatremère de Quincey, however, are equally admirable for their clearness and profundity. Sainte-Beuve, George Sand and others show profound insight, but only in parts; a whole is still wanting. In Germany it is received as one of the branches of philosophy, has its professors, its treatises and systems, and every man, woman and child is more or less imbued with it. Lessing, Winckelmann, Herder, Goethe, Schiller, Kant, Schelling, Novalis, the Schlegels, Tieck, Jean Paul, Solger, Hegel are among the great stars which illumine this atmosphere, but their separate endeavours are too comprehensive to be even mentioned here. Solger and Hegel may both be consulted for the historic portion. Lessing's works, though mostly polemical and directed against the French poetry, yet contain much that is true and admirable for all times, especially the "Laocoon." Winckelmann's works are much spoken of, unfortunately little read. Jean Paul's "Vorschule" does not pretend to be systematic, but it contains some charming writing, illustrations and close argument. His remarks on wit and humour are well worthy of study. Solger can be recommended to those who are content to view the matter in its abstract logical shape, unrelieved by applications and illustrations. The essays of Schiller, though rather repulsive at first from their Kantian rigidity of form, yet contain important ideas, and occasionally go to the very depths of the subject. But while all these works are more or less known and talked of in England, the masterly and comprehensive "Lectures" of Hegel remain without even the most vague and general notice.

**Simon Lantara.**

The French landscapist Lantara was the son of peasant parents, born at Oncy in 1729—was brought up as a herd-boy—brought forward by Gillet de la Renommière, the great man of the neighbourhood—and by a member of the family placed under a master at Versailles, having displayed on the walls of his stable signs after their kind as unmistakable as the Greek quotation which led Coleridge's commanding officer to suspect the so-called Comberback a trooper fit for better things than littering cattle. From Versailles the boy passed to Paris, and there, it seems, established a reputation, not merely for cleverness of hand, but for conviviality and sharpness of tongue. The old story, which has done service in the lives of so many different artists, of the fly as living as life which the pupil painted on a picture in the absence of his master, is among M. de la Chavignerie's collections to Lantara's credit. Another anecdote, quoted from Lenoir's "Dictionary of Conversation," is also not unfamiliar:—"A nobleman gave Lantara a commission for a landscape, in which there should be a church. The painter, like Claude Lorraine, did not know how to paint figures. The amateur, on receiving the picture completely finished, enchanted with the truth of the landscape, the freshness of the colour and the simplicity of the touch, said, 'M. Lantara, you have forgotten the figures in your picture.' 'Sir,' was the painter's ready reply, 'they are gone in to mass.' 'Very well,' was the patron's rejoinder, 'I will take your picture when they come out again.' Lantara is fathered with the well-known drinking-song, "A boire je passe ma vie." For the reputation which he bore of being one of those good fellows at a tavern, "who are no one's enemies save their own," he was served up by MM. Picard, Barré, Radet and Desfontaines as hero of a sentimental vaudeville, which was played and sung with great success in 1809. He died with a joke on his lips in the hospital of La Charité, in 1778. During his last illness he used to make little drawings on cards, says M. Lenoir, "and exchange them for lumps of sugar, sweetmeats and other dainties."

**Maclise's Portrait of Sir John Soane.**

Sir John Soane having been a large subscriber to the Literary Fund, some desire was manifested to have his portrait placed in the committee-room, and Maclise generously offered to paint it for the society gratuitously. Sir John accordingly sat for his likeness, and for a time it was pronounced to be perfect, both as a work of art and a complete resemblance. Some good-natured friends, however, got round the old architect and, with marvellously kind intentions, persuaded him that, while the Adonis-like charms were concealed, the defects and wrinkles of eighty years were too prominently put forward by the painter; assured him, while they shook his hand and swallowed his wine, that he was caricatured, not portrayed; libelled, not limned; and worked up the poor old man to a state of desperate rage with himself, Maclise, the Literary Fund and the whole world. Frantic with passion he demanded that the committee, on pain of his ceasing ever again to subscribe to the funds of the society, should immediately take down the offending likeness, whose libel was its truth, from the walls of their room and hand it over to him, while at the same time he offered to replace it by a copy of his portrait by Sir Thomas Lawrence. To the latter part of the offer no objection could well be made, but Maclise demanded back his portrait, while Sir John strenuously insisted that to himself alone it should be given. The committee were thus placed in a dilemma. They did not wish to offend Sir John, but they felt that it would be grossly unjust to Maclise if they refused to give him back his portrait. While they were deliberating a poor, half-witted fellow who had by some means heard of the controversy put an end to the dispute in the simplest manner possible. Having surreptitiously obtained admission into the committee-room late in the evening he cut the portrait into pieces and then went away, leaving a note on the table to the effect that he had destroyed the bone of contention. It was at first proposed to indict the offender for felony, but Maclise generously had pity on the wretched man. So extraordinary an occurrence furnished food for table-talk in London for a considerable period and gave rise to a hundred epigrams.

**Record Reign Inventions Competition.**

SIR,—We are exceedingly obliged for the very kind notice you have put in your valuable paper respecting *Western Mail* inventions competition. Unfortunately, however, a little error has crept in to which our attention has been called. The *Western Mail* is a *Cardiff* paper and not a *Plymouth*. If you will kindly refer to our letter we think this is clear. Perhaps

you may be able to oblige us with a very short reference to this matter in a coming issue in which you will correct this error. Thanking you for your kindness in this matter.—Yours faithfully,  
(GEO. H. RAYNER) RAYNER & CO.

37 Chancery Lane, W.C. : April 24.

**Royal Institute of British Architects Elections.**

SIR,—The fact that sixty existing members (out of sixty-four) have nominated themselves for the standing committees should be widely known. The best thing to be done under the circumstances will be to "plump" for new candidates, as in any case a large proportion of existing members must necessarily be returned. As seventeen of the existing Council are renominated for eighteen seats, it is desirable that all members vote, and for new men only. The existing seventeen members will no doubt be well looked after by their own friends; as they have renominated themselves, they will probably also vote for each other, but a few of them should give place for new blood.—Yours faithfully,  
A LONDON ASSOCIATE.

April 27, 1897.

SIR,—A doubt has been expressed as to the accuracy of the statement that a large proportion of the members do not vote at the annual elections for the Council. The following are the actual figures from the Institute Journal in reference to the last election:—

There were only 468 envelopes sent in containing the voting papers, and 29 of these were spoiled by informalities; no candidate obtained more than 391 votes, although the total number of members with voting powers was then 1,581, therefore no less than 1,113 neglected or refused to send in voting papers.

It is to be hoped that there will be more voters this year and that they will consider six new members of the Council, with twelve old members, a fair proportion.

The best way to secure this result would obviously be to "plump" for new candidates only, for it is absolutely certain that twelve, at least, of the existing Council will be returned.—Yours faithfully,  
A METROPOLITAN FELLOW.

London : April 28.

**GENERAL.**

**Messrs. Partridge & Cooper** announce that they will shortly publish an illustrated souvenir of the Queen's Diamond Jubilee, entitled "Temple Bar and State Pageants, an historical record of State processions to the City of London, and of the quaint ceremonies connected therewith, written by Mr. Henry Johnson, illustrated with pen-and-ink sketches by Elsie M. Cluff." The illustrations will likewise include reproductions of several interesting engravings in the British Museum.

**A Reredos** is to be erected in the parish church, Littlehampton, as a memorial of the late vicar.

**The New Town Hall** which the Vestry of Rotherhithe have erected was opened on Wednesday. The building will cost about 20,000*l*. It is in the Renaissance style, and has been designed by Messrs. John Murray & Frank Foster, of John Street, Adelphi. The builder is Mr. Howell J. Williams, formerly a county councillor for Rotherhithe.

**A Memorandum** was presented to the Salisbury Diocesan Synod on Wednesday, stating that during the last twelve months more than half the parishes in the diocese had generously contributed to the fund for the repair of the tower and spire of Salisbury Cathedral. In the Archdeaconry of Sarum the amount collected was 402*l*.; Archdeaconry of Wilts, 229*l*.; Archdeaconry of Dorset, 371*l*.—total, 1,002*l*. Altogether the fund now amounts to 11,500*l*., and 3,500*l*. is still needed to complete the work, which Sir Arthur Blomfield reports to have been up to the present time "accomplished in the most workmanlike and satisfactory manner."

**The Decorations** of the choir of St. Paul's Cathedral, on which Mr. Richmond has been assiduously engaged during the past six years, are now practically completed, and the work on the quarter domes will be at once taken in hand.

**The Interior** of Her Majesty's Theatre owes much of its effect to the co-operation of S. J. Waring & Sons, Limited, of Oxford Street, W., Liverpool and Manchester. The firm produced the splendid proscenium curtain, the carpets and the upholstering in the stalls, boxes and dress-circle, which impart colour and other advantages to the house.

**A General Meeting** of the Royal Society of Painters in Water-Colours was held on Monday, when Mr. Napier Hemy, Mr. Samuel T. G. Evans, Mr. J. Henry Henshall and Mr. J. R. Weguelin were elected members.

**The Architectural Association**, which was constituted fifty years ago, will hold its jubilee banquet at the Trocadéro Restaurant on Wednesday, May 5, at 7 P.M. Mr. A. Beresford Pite will preside. The guests include the Lord Chief Justice, the Bishop of London and Viscount Halifax.

# The Architect.

## THE WEEK.

THE terrible catastrophe which occurred in the Rue Jean Goujon on Tuesday is enough to extinguish the gaiety of Paris during many a day. It becomes, if possible, more awful when all the preliminaries are considered. The most admirable arrangements which were inspired solely by the desire to increase the revenue of the charitable society have brought about the calamity. It was the first time the Bazar de la Charité was held in the Rue Jean Goujon, one of the streets in the neighbourhood of the Palais de l'Industrie, where the last Salon exhibition is now open. Hitherto it was found in the Rue de la Boétie on ground belonging to a relative of the French President. By substituting the Rue Jean Goujon a sum of 200*l.*, which would have to be paid as rent, was saved, and that determined the migration. The honorary president of La Charité, Mr. HENRY BLOUNT, who is one of the worthiest representatives of England in Paris, was anxious to discover attractions on economical terms. He remembered the reproduction of Old Paris, which had served its purpose in the recent Theatrical Exhibition in the Palais de l'Industrie, but was not destroyed. Mr. BLOUNT secured it for 180 francs, or about 7*l.*, and M. CHAPERON, the scene-painter, who erected it, offered to touch it up without any cost. The space occupied by it measured 80 metres by 10 metres. As there was much more space available it was decided to instal a cinematograph close to Old Paris with its twenty-two booths, and to that installation the catastrophe must be ascribed. The only result anticipated by the founders was the receipt of at least 40,000*l.* The loss to the poor of Paris is therefore serious, but that will not receive much consideration at present.

ACCORDING to the report of the Art Union of London, there was an increase of over 100 subscribers in the past year. The amount of subscriptions enabled the Council, after setting aside 1,742*l.* for the production of the annual work, to appropriate 616*l.* for the purchase of prizes to be drawn by lottery, making, with those awarded as "consolation" prizes to unsuccessful members of ten consecutive years' standing, a total of 204 prizes. Mr. KIMBER, M.P., the chairman, said the Council had had exceptional difficulties to contend with during the past year, but, notwithstanding these difficulties, and the severe competition which had been encountered, the Society had been able to more than hold its own. The number of new members had more than counterbalanced those who had dropped out, and they had added to the subscription list by over 200*l.* The reversal in the House of Lords of the decision of the Court of Appeal in favour of their claim to exemption from parochial rates had, however, caused a serious inroad upon the funds during the year. The Council continued to offer only the very best works to the members of the Society, and for production as the annual work next year they had secured the copyright of Mr. EDWIN ABBEY'S dramatic picture, *Richard, Duke of Gloucester*, and the *Lady Anne*.

It appears almost incredible that a temple near Athens which was known to STUART and REVETT no longer remains be above ground, and that much trouble should have to be taken in order to discover the site. This temple, which was dedicated to DEMETER, stood on the left bank of the Ilissos. The style was Ionic, and it resembled the Nike Aptēris. When the French ambassador, the Marquis DE NOANTEL, visited Athens it was used as a Greek church, but he was able to have a mass according to the Roman ritual celebrated at the altar. On that account it lost its sacredness in the eyes of the Greeks, and it ceased to be one of their churches. It was therefore neglected, and by 1821 all the stones were used for other purposes. A windmill was erected on the site. Some Greek archæologists have succeeded in determining its position, and probably a plan of the foundation can be prepared. Judging by the number of fragments of votive tablets which have subsisted, the temple of DEMETER was at one time much honoured.

THE Special Committee appointed by the Government to consider "Where, in what manner and at what probable cost, provision may be best made for housing and exhibiting the art collection recently bequeathed to the nation by Lady WALLACE, and to make any recommendations which may seem fit to them as to the constitution of a trust in which this collection may be vested," will consist of the following members:—Lord LANSDOWNE (chairman), Sir WILLIAM HARCOURT, Sir EDWARD POYNTER, Mr. FREEMAN MITFORD, Sir F. MOWATT, Mr. WALTER ARMSTRONG, Director of the National Gallery of Ireland, Mr. ALFRED DE ROTHSCHILD and Mr. ALFRED WATERHOUSE. It is not often an architect is selected to take part in Government commissions, but in this case it could hardly be avoided. There is, it will be observed, no representative of the Science and Art Department on the committee.

At Meron, near Angers, the remains of a Roman temple have been discovered. The French peasants are not enthusiastic archæologists, and as soon as the foundations were seen the people of the district lost no time in seeking for treasures. Some coins were discovered, and as they were rare the prices obtained for them increased the eagerness for further explorations. Not the least regard was given to the old masonry, from which it would have been feasible to prepare a plan of the temple. Now much will have to be derived from imagination. The Conseil Général, apprehending additional mischief, has appealed to the administration for interference. After some delay money has been granted to the departmental commission for the purpose of ensuring the safety of any masonry that has survived.

AMONG the aids for decoration which can be generally employed during next month's festivities, we have not seen one which is so suitable as the Commemoration Shield prepared by the Anaglypta Company, Limited. As our readers know, the material from its toughness, endurance and consistency is capable of being utilised for reliefs which shall have as much sharpness as any in stone, and it is evident that for the design of the shield a sculptor was commissioned. In the centre is a bust of Her Majesty on a medallion surrounded by a ribbon with the motto of the Order of the Garter, with the lion and unicorn as supporters. Above are the dates 1837-1897 on each side of the royal crown, while below is the shield with the quarterings relating to Great Britain and Ireland with national emblems on either side. All the details could not be more creditably executed by the medallists of the Royal Mint with the aid of the College of Arms. The shield is 42 inches square, and is produced in gold and colours at a most moderate price. By itself or as the principal element in a trophy formed of flags the shield is a very attractive piece of decoration, and it merits to be used throughout the country during the festivities, and to be preserved as a memorial of so memorable an occasion.

THERE is a contest between the administration of Fine Arts in France and M. DANIEL DUPUIS the medallist. He was commissioned to prepare a model for the new bronze coinage which is about to be issued. It is no easy task to satisfy the authorities when they have to deal with a subject of the kind, and M. DUPUIS must possess exemplary patience or he would never have submitted his work to such a long series of trials. At last he was compelled to rebel. On one side of the coin M. DUPUIS has modelled a head in profile of the Republic, with a phrygian cap on the head. Very few alterations were asked for on the obverse. But on the reverse the artist has represented a figure symbolic of France, holding an olive-branch in the left hand, while the right grasps a flag which shelters a child carrying a hammer and a sheaf of wheat, being, in fact, the representative of labour. Twenty times the reverse has had to be altered, and yet the authorities are not satisfied. They wish to have the baby labourer removed. M. DUPUIS has refused, and it remains to be seen whether the Department of Fine Art will respect an artist's rights.

## PAINTING AT THE ROYAL ACADEMY.

THERE has to be such incessant production in our time, little leisure is allowed for thinking or invention, and accordingly in the arts, as in the commonest machine-work, monotony prevails. This applies especially to painting. In consequence, every one who is accustomed to visit modern exhibitions is able to form a tolerably correct notion of the contents of a new exhibition before he sees them, if the names of the artists are given to him. Indeed, anticipation is more easy with painting in this country than with any other form of art. Public opinion, which is supposed to be an infallible authority, generally determines to its own satisfaction what variety of subjects a painter is competent to treat, and purchasers, who as a rule are incompetent to judge, prefer works which will correspond with the public verdict. In a large collection such as we see every year in the Royal Academy we have therefore to encounter many pictures with which we somehow seem to have been a long time acquainted, and it is unnecessary to refer to the catalogue to ascertain by whose hands they were produced. If the exhibitions consisted solely of those works a visit would rarely be a pleasure to any one who was not a novice in picture-seeing. But happily there are artists whose grooves are not yet assigned to them—some who are ready to revolt against what professes to be authority, others who love experiments, and, lastly, those who are only feeling their way. Thanks to them, there is occasionally a chance of seeing something that compensates for the inevitable monotony which is one of the consequences of our social organisation, and this year the number of novelties is larger than usual, and some might be considered as surprises.

Before mentioning any of the works in question, it may be well to remark that a sort of novelty is imparted to this year's exhibition by the number of pictures of military subjects. A few years ago it was with difficulty an occasional work of that class could be discerned. Now they form an important proportion, and, what is more remarkable, they appear to be well appreciated by visitors. Among them may be mentioned *Quatre-Bras*, by Mr. V. HAMILTON; *the Attack on the Gatehouse of the Château of Hougomont*, by Mr. CROFTS; *the Captive Eagle*, by Mr. J. P. BEADLE; *Norman Ramsay at Fuentes Onoro*, of which there are rival versions by Mr. R. C. WOODVILLE and Mr. W. B. WOLLEN; *Nelson at the Battle of Copenhagen*, by Mr. T. DAVIDSON; "*Steady the Drums and Fifes!*" (the 57th—Die-hards—drawn up under fire on the ridge of Albuera), by Lady BUTLER (which is the most fitting of the painter's works to be a pendant to the *Roll Call*). That war is not always without a humorous side is suggested by Mr. W. C. HORSLEY'S *Incident of Napoleon's Egyptian Campaign*, in which we behold a party of the French *savants* and their *demi-savants* (or donkeys) about to be enclosed within one of the infantry squares as an attack of Mamelukes was impending. NAPOLEON is also the subject of other pictures. Mr. GOW gives us a glimpse of the Emperor on his way to surrender himself to the English captain; while Mr. H. H. PIFFARD shows his *Last Review*, the troops being a little boy and girl, children of the faithful BERTRAND. In these works the usual sympathy with the fallen chief is exhibited.

In the first room the work of the Spanish painter JOAQUIN BASTIDA asserts itself among its companions, not only by the subdued gold frame but by the vigour of the handling. A *Segovian Family* shows the interior of a room with a few poor people at work, and the brilliant light which falls on them seems to elevate them in character. Very few colours are used, and yet the picture is impressive from colour alone. Mr. R. NOBLE'S *Golden Harvest Time* appears to be taken from a Scottish scene, for in England we are not familiar with a meadow which lies between a great lake and a wood, and which an old castle guards. The hot haze of autumn dominating such a scene is ably rendered. Mr. HACKER'S biblical scenes are rarely conventional. *And there was a Great Cry in Egypt*, although only a single figure is shown, is most impressive, for the angel to whom is entrusted the charge of smiting the first-born seems appalled with his task. EBENEZER ELLIOTT'S *Angel of Eternity*,

With his wings of sorrow and affright,  
Veils his impassioned brow and heavenly tears,

but the Angel of the Exodus hides his sorrow under a brown veil. The figure is placed diagonally across the canvas, and seems as rigid as the long sword which is borne, and to be equally, if involuntarily, an instrument of destruction. Did the hangers wish to suggest the difference between Greek and Semitic theories of life when they placed Mr. G. W. WETHERBEE'S *Aphrodite's Realm* above the Scripture piece? The little amorini who are joyously disporting themselves in waves which appear as if never likely to be subjected to a storm, are a sort of symbol of a Greek's notion of life and religion. Mr. JOHN FINNIE'S *A Tragic Sunset* is forcible in every way, but it is one of the very few pictures which might be cited this year as not creditable to the hanging, for we must say that delicate operation has been conducted with rare equity towards outsiders. If the County Council of London were wise, they would secure, if possible, Mr. DAVID MURRAY'S three large views of *Hampstead's Happy Heath*, and hang them where the poorest as well as the rich could see them. The paintings would be more serviceable than paid officials in revealing what art can do, and what lovely natural scenes are to be discovered in Cockneydom by all who have eyes to see. Mr. OLSSON'S *Golden Shore*, a range of red cliffs, are also worth attention. Mr. LA THANGUE gained notice by his treatment of light and shade, and his *Travelling Harvesters* displays that power to a remarkable extent; but the *Summer Morning*, although wanting in strong effects of that kind, is likely to afford more constant pleasure. The boy, whose bait has succeeded, is probably more surprised than the gudgeon that is hooked. We hope the artist will not allow himself to be coerced into a sort of daylight WRIGHT of Derby, and will paint many summer morning scenes in which no one quality is made predominant. Sir GEORGE REID'S *Professor Mitchell* is one of the most telling portraits in the exhibition, but the subject has much of the appearance of one of those stealthy officials who are always dropping on youngsters in French schools. Mr. GUNNIS'S *A Spring Cleaning* would be welcome for its humour alone. It represents the agony of a professor who discovers his violins in the wash-tub, but the greys and white are excellently combined.

In Gallery II. Mr. F. A. BRIDGMAN, the American painter, shows a departure from his customary Eastern scenes (*Arabs Bathing Horses* in Gallery IX. is a good example) in his *Bacchante*, in which the revellers assume a decorative arrangement without any loss of spirit. It was a difficult subject to paint, and the artist has succeeded. Mr. ALFRED PARSONS is fond of evening scenes, but he generally prefers lowland spots. In *The Star that bids the Shepherd fold* he shows the side of a hill with many boulders, with a shepherd gathering his flock. The calmness is not less marked than in the earlier views. Mr. J. W. NORTH'S *The Old Abbey Fishpond—Morning in March*, is also a departure from his usual preferences, but habit is powerful and it would take very little work to make the picture represent a morning in autumn. The *Love's Baubles*, of Mr. B. SHAW, girls following Cupid, is very brilliant in colour and almost elaborate enough in detail to satisfy a pre-Raphaelite. It is not right to suggest a goddess could be tired, but that is, we suppose, what Mr. ARTHUR WARDLE in his *Diana* wishes to suggest. If considered as an ancient huntress attended by sympathetic dogs the picture is delightful. M. BENJAMIN CONSTANT'S *Earl of Ava*, the portrait presented to Lord DUFFERIN by the English Colony in Paris, is a remarkable feat as a representation of an Englishman by a foreigner, in which no foreign characteristics are introduced.

Mr. C. NAPIER HEMY has, by means of his *Pilchards*, drawn one of the prizes which are so eagerly desired. It is not merely that the picture will be included in the Chantrey Collection, for selection is not always a proof of merit; what is more advantageous, the public are impressed by the treatment. We cannot remember seeing a picture as large by the artist, but many of his smaller works were no less able. In *Pilchards*, as in his other works, there appears to be a fisherman's delight in a haul, and it suggests that Mr. Hook may be considered as the founder of a school in which Mr. NAPIER HEMY, Mr. COLIN HUNTER and others have been worthy pupils. Mr. LOGSDAIL'S *Bronze Horses of St. Mark's, Venice*, suggests how different a subject may appear when seen closely from what it appears from a remote point of view. The picture corresponds exactly with THEO

GAUTIER's description of the horses as "airain de Corinthe, dont on voit la patine verdâtre à travers un vernis de dorure écaillé par le temps." Mr. BOUGHTON, who has so long succumbed to the call for namby-pamby figures that, judging from his diploma picture, *Memories*, he must believe his vocation is to produce them, emancipated himself while painting *After Midnight Mass, Fifteenth Century*. It represents a part of a varied congregation leaving a church when snow has fallen, and the grand folks have to be lighted on their way by torches. Technically, it cannot be supposed there could be so much clearness of illumination with torchlight, but there is the advantage of seeing the most interesting collection of figures which the artist has produced of late years.

Gallery IV. contains what is likely to be the most popular picture of the year, viz. Mr. E. J. GREGORY's *Boulter's Lock: Sunday Afternoon*. We hope it will have a place within the English section of the International Exhibition of 1900, if it were only to convince foreigners that perpetual fog does not overhang the environs of London, that English folk do not always occupy their Sundays with tribulation, and do not take their pleasures sadly. There is so much faith in Mr. GREGORY's powers, the picture, beautiful as it is, may not after all correspond with the expectations of his friends. It has the disadvantage of appearing as a combination of portrait groups, and the excess of pink is rather fatiguing. But it was no easy task to paint so many people in a sort of prison, for what else is a narrow lock-chamber, without a suggestion that they were momentarily deprived of liberty? Activity and repose had to be also combined, the Sunday costumes of women with the *déshabille* of men. The light that beats along the lock is also to be supposed as adding brilliancy to the colours. We should also remember that after all the scene depicted is commonplace, and only the finest tact could make it attractive. We ought to be thankful for such a revelation of beauty, but Mr. GREGORY has the knack of exciting anticipations which probably can never be realised on canvas with ordinary paints. Near a picture in which red prevails the advantage of green is manifest, and it was a happy thought to hang Mr. YEEND KING's *The Garden by the River* on the same wall with the lock scene. The *Colt Hunting in the New Forest* by Miss KEMP-WELCH is one of the surprises of the year. The subject was treated before, but never, so far as we know, on so large a scale. Like the *Boulter's Lock*, it will reveal to strangers that this country is not given up entirely to factory-life. Powerful animals like those which appeared in Middle. ROSA BONHEUR's two great pictures are not introduced, but, on the other hand, there is more variety of animation, and as the figures are not seen in profile, as in the French artist's work, more skill was needed to make the group effective. Skill which merits recognition is also seen in Mr. A. P. BURTON's *Night Fleeing from Dawn*, in which a nude figure appears that suggests flight. Mr. F. DICKSEE has treated the same subject in his *Dawn*, but with a less display of technical power.

Mr. E. BUNDY's *Puritans* in Gallery V. shows one of those assemblies for prayer and preaching which increased the resolution of reformers. The men are gathered round a table in a room, and so remarkable a collection of heads will not be found in any other picture this year. The creation of such a number of varieties was no easy task, and they all seem to be true to nature. Mr. STANHOPE FORBES has painted forges and other scenes of country life. In *Christmas Eve* he has ventured to grapple with so mean a subject as a back street in a town, with the "waits" playing outside a public-house. The contrast which the artist's favourite bluish-grey would offer when opposed to an ophicleide and other brass instruments was, we suppose, the original temptation. It is a novelty for Mr. FORBES, but the subject was not worthy of so much labour. Signor BACARISAS' *The Corso, Rome*, however, gains in interest when we see it near so chilling a street view. *Evening after a Hot Day*, by Mr. H. SWANWICK, represents farm stables, with two tired grey horses and a brown about to drink. The slowness of their pace and the weariness of the boy guiding them, with the dull light on the ground and walls, are enough to suggest the character of the scene if the title were not given. In Mr. SWANWICK agriculture has found an illustrator who appears to have a familiarity with

country life which is hardly possible with a townsman. Among the "new departures" of the year there is not one so remarkable as Mr. J. C. DOLLMAN's, for he has attempted the *Temptation of St. Antony*. Flemings and Dutchmen used to make it a favourite subject, and the finest of all interpretations of the legend was by a Fleming, GALLAIT, of Brussels, who died a few years ago. In that work human weakness was not ignored, for the hermit appeared afraid of the spectre. In the English picture the saint is seen kneeling before a cross which is in a recess of his cell, a light being near it which is reflected in the eyes of the monkeys and other beasts which form a circle round the principal figure, which is that of a woman as fully displayed as the *Phryne* of M. GÉRÔME. He gazes steadfastly on the cross, and is apparently unconscious of the trial awaiting him. The old painters have not as a rule allowed St. ANTONY to remain free from positive coercion by the enemy, and Mr. DOLLMAN's drama scene may, therefore, appear incomplete. But we can imagine the coercion was of a mental and invisible sort, and the picture gains by the departure from tradition.

Mr. ABBEY's feat last year has incited him to produce another Shakespearean illustration of an original sort. It is less easy to understand his *Hamlet* than the *Richard Duke of Gloucester and the Lady Anne*. In the picture we see the spectators at the play scene, but not the players. It is therefore absurd to compare Mr. ABBEY's work with MACLISE's. The new work is moreover less complete in an æsthetic sense, for there is nothing to suggest why CLAUDIUS, GERTRUDE, OPHELIA and others should be gazing into vacancy—that is, towards the spectator. Then, again, why should the king and queen be painted with their heads touching the frame of the picture, and in fact all the figures cabin'd, cribb'd, confined, as if they were puppets in a box? We assume that Mr. ABBEY was desirous to suggest that as the story of the poisoning of HAMLET's father was related by SAXO GRAMMATICUS, therefore a thirteenth-century appearance should be given to his picture. But the artist might have known that thirteenth-century illuminations are not remarkable for the restrictions of space when there are incidents to be depicted. The old miniaturists made no fuss about adapting figures to fill very narrow or very awkward spaces. But in important scenes they suggested spaciousness. One aid towards producing the effect was the introduction of pieces of furniture, or most careful showing of the architecture. It is well known that illuminated manuscripts are, in consequence, of much use in determining problems about the appearance or details of buildings which no longer exist. Now, it is remarkable that although Mr. ABBEY apparently is inspired by archæology, his picture is without any object which would suggest that it was the work of a past age. The seat on which CLAUDIUS and GERTRUDE are placed is concealed, while a Mediæval artist would have a beautiful throne. We do not insist on the necessity of thirteenth-century surroundings—the attempt to introduce them has been injurious on the stage—but if they are employed they should be correctly employed. We suppose it is to keep up the archaicism that most of the faces appear inane, and OPHELIA becomes an idiotic spinster. SHAKESPEARE would be dumfounded if he could see the picture, and then he would be likely to enjoy it for its novelty of interpretation. He expressed in "Hamlet" the latest thought of the age; the prince was a student of Wittemberg, and he represents the transition from Mediæval knowledge to modern science. The Danish HAMLET was a man of a different class. Remarkable as is the picture, we cannot consider it as in any way helping us towards a clearer understanding of the tragedy than is possible with the aid of earlier pictures. Mr. PHIL MORRIS in *The Builder's Daughter* depicts one of the legends of the origin of the Prentice's Pillar at Roslyn, and instead of a competition between apprentice and master suggests the carving was a lover's testimony. It is not often we see DON QUIXOTE and his squire of late years, and Mr. ARTHUR LEMON's picture of the delay on the roadside when the sceptical SANCHE PANZA declares, "The devil of any knight, giant or man can I see of all those you talk of now," is therefore a pleasing addition to the collection.

(To be continued.)

## ARCHITECTURE AT THE ROYAL ACADEMY—II.

**H**ITHERTO Messrs. AUSTIN & PALEY, of Lancaster, have held aloof from Academy exhibitions, but this year they have given way to the common weakness. They contribute a view of the proposed church of St. Thomas, St. Anne's-on-the-Sea, a long regular church with two windows between each buttress and a very slight belfry, and three views of a more important building—St. George's Church, Stockport—which in every part reveals the hand of a designer who has had abundant practice. St. George's is Perpendicular, with a tower having panelled faces and a tall spire, the lines of which combine with the tower by means of small arched buttresses, and therefore the abruptness which is common is avoided. The roof of the nave is open timbered. The altar is placed in a recess, and the choir has a groined roof. It is a costly building, and a dignified appearance has been imparted to it by the architects. In Hillmorton House, Rugby, light brick and red brick are combined by Mr. SUGDEN, and, judging by the breadth of the windows, the rooms must be low. The Design for Wrought-iron Gates for Dacre Court, Buckingham Gate, by Mr. C. J. C. PAWLEY, from the alternation of plain bars with ornamental masses of similar dimensions, is much more effective than if ornament alone were presented. There is a suggestion that constructive needs have been met which is not apparent in many elaborate gates.

Mr. WATERHOUSE's only contribution to the Architectural Room is the Surveyors' Institution, which occupies a corner site at Westminster. In it terra-cotta is largely used, and as usual verticality is markedly expressed by the mouldings. There is, too, a very elaborate cornice. The capacious size of the windows suggests that the theatre or hall is to be used by day as well as night. The design has all the strength that is customary in the architect's buildings. Justice does not appear to be rendered by the draughtsman to Messrs. MURRAY's Church of St. Saviour, St. Leonards-on-Sea, which we suppose to be more picturesque in reality than on paper. From the large size of the west window of Mr. MOUNTFORD's Church of St. Michael, Southfields, Wandsworth, and the smallness of the other windows, the building, we suppose, is mainly lighted from the ends. The small detached vestry at right angles is rather quaint. Holy Trinity, Southport, by Mr. HUON MATEAR, will be an important addition to the numerous churches in that town. It is boldly symbolic, for the tracery of the great window is arranged in cruciform lines, and in the gable is a sculptured representation of the Crucifixion. The Manx and other crosses introduced at the foot of the building help out the meaning, which is expressed, moreover, by a very vigorous drawing. Mr. C. F. A. VOYSEY is a believer in the moral effect of a severe simplicity in residences. The House at Guildford might be covered with whitewash, and the windows could hardly be plainer. The only concession to those who dislike to live in boxes is seen in the carrying down of the green slate roof almost to the ground—an arrangement which is not economical. There is not much use in an Academy exhibition if all the drawings cannot be studied. The Academicians in their desire to oblige do not consider that purpose, and as miniature drawings do not appear dignified in the lower strata they are placed as high as possible in positions where they cannot be examined without the aid of ladders. Mr. HUNTLY GORDON's Shops at Teddington Bridge, a group partly in half timber, is one of the sufferers. The Design for Meffan Institute, Forfar, by Mr. T. M. CAPPIN, is, like his hotel, remarkable for the absence of local characteristics. Mr. BELCHER at one time used to secure more wall-space than the majority of exhibitors. This year he has only three small drawings: one represents the stalls, organ-case and screen for Kineton Church, Warwickshire—a study in colour rather than form; the second is a dining-room that recalls NASH's lithographs; and the third is a Design for a Mausoleum, which has a dome and is rather heavy. Mr. D. JOSEPH's South Hackney Synagogue is like a commonplace City church with galleries, but there is more of the Moorish style about the exterior of his Cardiff Synagogue. Mr. E. GOLDIE has a fine Gothic interior, St. Alban's, Blackburn. The piers are made slight in order to afford no interruption to the view, and there is a general

air of lightness. There is also a revival of the reredos, a feature which of late was generally superseded in Roman Catholic churches. Hawkesyard Priory is a large and important group so arranged that the chapel appears to have most importance. Mr. H. BRAKSPEAR's Remodelling of Chancel, Lacock Church, is suggestive of massive if not heavy details, which, we suppose, are in keeping with the rest of the building. Mr. H. REDFERN has a gate-house and master's lodgings, Abingdon School, which have a sort of old-fashioned simplicity that dons hardly appreciate nowadays. Mr. JOHN BROOKES' Parish Church, Handforth, is a type of a good village church. The Rood Screen, Blisland Church, Cornwall, by Mr. F. C. EDEN, is a sort of a structure which appears to be now preferred. The screen is close to the altar, and from its character must obscure the chancel, while above it is a substantial gallery or rood loft with a Crucifixion, winged figures being substituted for the customary figures. The Memorial to the Countess DUCIE, designed by Mr. CARÖE, consists of a screen with seats, to which a ruin serves as a background. Mr. SHINER's Memorial of the late J. THEOBALD, M.P., shows the apse to Grays Church, the windows being varied in treatment. In Messrs. PARKER & UNWIN's Living-room, Woodcote, timber is employed so liberally that those who are seated in the ingle-nook can easily imagine they are in a sort of prehistoric dwelling. Mr. S. PERKS is another contributor of a small half-timbered house. Mr. CARÖE's design for the Museum Extension, Liverpool, is Classic of the Liverpool type, the Corinthian Order being employed. It is in keeping with the original building. Mr. H. ROSE has a screen with figure and altars for St. Mary's, Chaddesden. Mr. G. H. SHACKLE's design for a church in Exeter shows a tower near chancel. Generally the treatment shows more severity than is to be found in the older exemplars in Exeter. Mr. W. RAVENSCROFT's House and Stabling at Maidenhead is more suggestive of some large institution requiring a wide landscape to develop itself in than a family dwelling-house. Whetton Court, Salop, by Mr. H. E. FARMER, is another example of needs which are not to be satisfied in a restricted space, for it appears to form a terrace of three houses. A third large house is The Shotts, Dartmoor, by Mr. T. H. LYON.

Mr. A. H. SKIPWORTH shows designs for two churches—St. Aidan's, Walton-le-Dale, and Cockington, Devon. The latter is the more costly, and much thought has been evidently given to details. The polygonal belfry, surrounded with shields for armorial bearings, is a picturesque addition. Mr. J. J. STEVENSON, in his Houses in South Street, Mayfair, appears to have renounced Queen Anne, and favours a sort of French type, with high mansard roofs and stone dressings. The three designs in one frame, by Mr. BERESFORD PITE, are interesting as examples of a free treatment of Italian, in which sculptured figures are essential; in the others we see mezzanines flanked by figures. The designs suggest that ordinary houses can gain a large increase of interest by such additions as are represented. Mr. H. T. HARE, in his Presbyterian College, Cambridge, has introduced much variety in the parts of the long range of building. Another design for the same work is by Mr. W. H. SETH-SMITH, but from the point of view taken it is more suggestive of a church than of a college. Mr. W. C. HARDISTY has a view of the chancel of Christ Church, Moss Side, Manchester. Mr. A. W. COOKSEY is represented by a design for cottage alms-houses, and Mr. J. H. SELLERS by a small country house. Mr. ASTON WEBB's Additions to Paddock House comprise a long range of conservatories and rooms with windows that are almost like walls of glass. The Kennington Road Public Baths and Wash-houses by Mr. A. H. TILTMAN have a good effect owing to the solidity expressed by the plain wall surface below. The upper windows are skilfully arranged. It is not often so luxurious a private chapel is met with as that in Douglas Castle, Lanark, which Mr. WHALL represents. All that marbles and painting can do to produce effect is visible. Messrs. ERNEST GEORGE & YATES, in No. 49 Prince's Gate, show a finely panelled dining-room with deep pilasters flanking doorway, windows and fireplace, and carrying an enriched cornice which is broken by consoles. The usual flatness of walls is therefore obviated. The window of the music room is no less interesting, but graceful Corinthian colonnettes are used to

form the bays. Another drawing by the same architects shows various views of the interior of Claridge's Hotel, which are treated so as to correspond with the purposes for which the rooms are designed. The New Buildings, Liverpool, by Mr. R. N. SHAW and Mr. J. F. DOYLE, are more severe and Italianised than would be imagined. The use of rustication and the small size of the window-panes suggest strength and endurance, but the projecting turret is, we suppose, intended as a compensation for the rigour of the lines generally. Holmwood, near Wimborne, by Messrs. CRICKMAY & SONS, is attractive mainly on account of the porch. Mr. H. WILSON's drawings are always noteworthy. The Staircase, Welbeck Abbey, is placed where it can be seen from the adjoining room. The marbles are well relieved by the red wall space. From the number of sloping lines Messrs. SILCOCK & REAY's Village Hall, Claverton Bath, at the first glance might be taken for an Egyptian work. Mr. R. S. BALFOUR's Institute of Architects won the Soane Medallion in 1895. It is a massive Classic building, but coldly Academic.

(To be continued.)

### THE GENERATION OF ELECTRICAL ENERGY FOR TRAMWAYS.

A PAPER with this title was recently read before the Institution of Electrical Engineers by Mr. J. S. RAWORTH, and, as the introduction of electric traction is now being contemplated by many municipal bodies, it may prove of advantage to review it. Mr. RAWORTH referred to the development of the dynamo, and stated that the object of the paper was to show that a paying price for the supply of electrical energy for tramways, under reasonably favourable conditions, was *one penny* per unit, and also that such a supply reduces the cost of current for lighting by a small amount. Referring to the steam consumption of an engine, he pointed out that Mr. WILLANS had told us that the consumption at no load is about one-third of that at full load with a constant expansion, non-condensing engine, and because of this the cylinders of engines were made smaller, and no margin was left for overload, as a waste of steam would be the result. In mentioning the fact that indicated horse-power is only a stepping-stone to the electrical engineer's goal, which is electrical horse-power, Mr. RAWORTH referred to the losses, per electrical horse-power, which, he said, could be improved considerably, (1) by increasing the efficiency of the engine and dynamo, (2) by using a condenser with the engine. Although the effect of the latter is considerably better than the former, in both examples there is considerable loss in working much below full load; and owing to this great care has been given to the design of electric-lighting stations and the working of the same by the subdivision of the plant, so that the loss due to engines working underloaded may be low. But he pointed out that this subdivision of plant has increased the complication of the steam-pipes and valves, which causes waste due to the condensation of the steam, and also means that skilled supervision is necessary in order that the plant may be worked economically by constantly changing the different sizes of engines.

The bearing of all this on the traction question, he said, is that some engineers have come to the conclusion that a unit of electrical energy for tramway purposes will cost as much if not more than for lighting, as they cannot change their engines as quickly as the tramway load changes.

He (Mr. RAWORTH), when comparing an automatic expansion with a fixed expansion engine (each taking the same amount of steam per indicated horse-power hour at full load), said that the automatic expansion engine has a better economy per electrical horse-power down to one-third full load than at full load, and even below one-third full load. The loss of economy is much less than with a fixed expansion engine. From curves that were shown it followed that an automatic expansion engine is more economical than a fixed expansion one at all loads, and that its greatest economy is at about  $\frac{1}{6}$  of full load. The practical application of this statement to traction work is as follows:—

As the average load remains fairly constant, and the momentary variations are as erratic as they are great, there is no advantage to be gained by the subdivision of plant. The problem, therefore, approaches the case of a mill, viz.

one engine large enough to do the work, and the solution will probably be similar, with, of course, a spare engine and dynamo, but this latter need not be kept under steam.

In assuming this solution adopted, he proposed to prove that electrical energy can be supplied, as previously stated, for 1*d.* per unit, and gave the case (as an example) of a tramway requiring 1,000,000 units per annum, taking the number of hours run per year to be 5,720, that is, allowing sixteen hours a day and fourteen on Sundays, and taking the plant to be provided to have a capacity of 470 electrical horse-power. He went into details with regard to the capital cost, cost of generation and management, and pointed out that not only can the energy be supplied at 1*d.* per unit, but a profit of 8 per cent. can be made. With regard to reducing the cost of the energy for lighting purposes by combining the two (lighting and traction), he pointed out that an annual saving could be effected, or sufficient to increase the profit on the traction plant to 10 per cent., or decrease the cost per unit for the traction to  $\frac{1}{8}$  *d.* In his figures only ordinary efficiencies had been allowed for, and coal had been taken at 10*s.* per ton.

He then referred to the problem of engine construction and pointed out that with electric traction, although involving sudden variations in load, there is no difficulty in arranging so that the maximum load shall not exceed the power of the engine, unless caused by short circuits, which are now minimised by automatic circuit-breakers protecting the dynamo, and therefore neither the strains nor the wear due to such causes will ever exceed those which are dealt with in electric-light stations.

Mr. RAWORTH's opinions may be summed up that high-speed automatic expansion engines of large size are the most suitable and economical for tramway working, but that the saving on the score of the lighting load is not very high. In the case he took the saving was sufficient to raise the profit on the traction plant from 8 to 10 per cent.

Looking at the part of the paper in connection with lighting, the headings under which he finds a saving can be effected are manager, boiler and stoker, but he does not mention any saving in connection with capital expenditure on buildings and electric-lighting plant, also any saving under running expenses of engine-room staff and outdoor staff.

The paper is excellent from a traction point of view, but no statement is made as to whether the same plant can be used partially for lighting; it ought, however, to be of considerable interest to borough engineers and surveyors in whose districts the conversion of the horse tramways into electric is being considered.

### THE ASSOCIATION JUBILEE BANQUET.

THE Architectural Association held its Jubilee banquet in the Trocadéro Restaurant on May 5, the president, Mr. Beresford Pite, in the chair. Among those present were the Lord Bishop of London, Viscount Halifax, Professor Aitchison, A.R.A., Mr. H. C. Richard, M.P., Mr. J. P. Seddon, Mr. R. Kerr, Captain Lambton Young, Mr. A. S. Murray, LL.D., Mr. T. M. Rickman, Mr. W. H. St. John Hope, Mr. Alex. Graham, Mr. Aston Webb, Mr. T. W. Goodman, Mr. J. Edmeston, Mr. J. Norton, Mr. T. E. Colcutt, Mr. H. C. Boyes, Mr. T. Roger Smith, Mr. J. Sulman, Mr. W. M. Fawcett, Mr. T. H. Watson, Mr. E. W. Mountford, Mr. J. Ely, Mr. Walter Crane, Mr. Leonard Stokes, Mr. T. Blashill, Mr. John Slater, Mr. E. P. Warren, Mr. C. Hadfield, Mr. W. Henman, Mr. S. Perkins Pick, Mr. F. W. Pomeroy, Mr. H. Devey Browne, Mr. J. H. Christian, Mr. W. D. Caröe, Mr. J. M. Brydon, Mr. A. W. Weedon, Mr. W. G. B. Lewis, Mr. H. Tanner, sen., Mr. J. Jacob, Mr. W. J. Cloake, Mr. E. Inigo Thomas, Mr. G. B. Carvill, Mr. Ellis Marsland, Mr. A. Wallace Rimington, Mr. J. K. Colling, Mr. J. Edmeston, and the hon. secretaries.

The President, in toasting the Queen and the Royal Family, said her Majesty had bestowed an infinite blessing on the production of the finest works of architecture, by the glorious peace which had been maintained with our relations and by the wonderful wealth with which her subjects had been blessed. If it had not been for these two benefits they would have been a scattered band of hungry architects.

The President, in proposing the toast of the Church, said the magnificent character of our national ecclesiastical architecture was the prime cause of the enthusiasm aroused in the breasts of Englishmen concerning the constructive art. When they came to the question as to what was due to the pre-eminent character of this art they were face to face with a difficulty in definition. With the Lord Bishop of London on his right hand

he ventured to suggest that the problem which united Church history and architecture in a knot, and which drew our admiration to cathedrals and village churches, was a subject which made them feel honoured in having his lordship as their guest.

The Lord Bishop of London, responding, said they were met either as architects or as people intimately connected with architecture; in fact, all men were under an obligation to architects, as all needed some shelter in houses constructed after their plans. To whatever profession they belonged, or whatever vocation they pursued, they all felt a debt was owing to architects. He thought there was a difference between the Church and other professions. Whereas everybody wanted architecture which was adapted simply and solely to convenience, the Church needed architecture adapted to the expression of ideas. Because the Church stood in that peculiar position, it had inspired those engaged in the architectural profession to erect the mighty works which one saw. A house was a building split up for convenience into small rooms; and even great buildings for municipal purposes, whilst affording artistic scope in their treatment, had to be split up into suites of rooms. The church was the only building which directly challenged the architect's skill. Outside and inside alike it was one mighty span, and offered space and largeness, which were absolutely necessary for the development of every great art. It was therefore that the church required, first, the exposition of ideas, and, secondly, that the mere form of its building should be large, spacious and splendid, thus calling upon architects, not only in their spiritual and moral nature, but also in their capacity in simple structural development, giving those opportunities which had been so worthily made use of in the past and also in the present. Since coming to London he had been struck by the resourcefulness of architecture in modern times. There was a time when he admired only the ancient in art, but he was fast becoming an admirer of modern construction. The great growth of London had given scope for the architect. Modern buildings, however, demanded a disposition of site unknown in the old days. The sites at the first glance appeared unfavourable, but he was struck with the capacity shown for using the small opportunities afforded, and adopting the land to the purpose for which it was needed. In the admiration of a past age it was often said that we to-day were not so artistic. He was not quite sure that if the history of our modern cathedrals were studied that conclusion would be arrived at. In the old days people were not in a hurry, and they did not require their buildings to be adopted to vastly growing populations, but were prepared to erect a building without regard to the surrounding community. Then the cathedrals were competing for pilgrims, and built purely as an advertisement in order that they might draw pilgrims from the other "shop" which was not so well adapted. A great deal of the history of our cathedrals was explained by this formula. First the choir and the nave would be erected, and as the work of some other part was proceeding news would be brought that a neighbouring establishment had gone one bay better, and in order not to be out of the race, the cathedral in course of erection would have to go one better, or the pilgrims would go over to the other place. The more the history of the Middle Ages was studied, the more one found the same prosaic and commonplace questions lay at the bottom of a good many minds. The clergy were not held in very great estimation by some of his hearers from a professional point of view, as they frequently stood to the architect in the relation of the employer of labour, and he thought an employer often embodied reminiscences of a vast amount of unintelligible criticism. Architects had a great misfortune in being subject to this kind of criticism. In the treatment of ecclesiastical buildings entrusted to them, architects were doing their best, and not only the work which was the result of the piety and genius in the past, but the construction of other buildings in the present would not be unworthy of their predecessors. In conclusion, he wished them all prosperity in the arduous undertaking they were engaged in. Clergymen felt their dependency on the skill of the architect, and he thanked them for the good they were doing on behalf of the Church.

Viscount Halifax, who proposed the toast of the Architectural Association, disagreed totally and entirely with the Bishop of London in that ideas were not necessary in the construction of houses. The one thing more necessary than another was that houses should express ideas, and he knew how much influence a house had on its occupants, and how much depended upon details, not merely for comfort, but also for a sense of well-being. He said there was no institution in England for which he wished a greater development than the Association. Dwelling at length on the object for which the Association had been founded, namely, voluntary and mutual instruction in architecture, he proposed the toast.

The President replied, and in the course of his speech narrated the history of the Association. He referred to the presence among them of Professor Kerr, who was president for 1847-48. Without the aid of the Association the Institute must have suffered. They possessed a large number of active

members, and their classes were well attended. But they still needed a home, a building which would be suggestive of the history of the Association. The temporary premises were overcrowded. The President proposed the Royal Academy, the Institute and Kindred Societies.

Professor Aitchison, in reply, said the Institute did what it could for architecture, but the Association had taken a more practical view of the art. He hoped architecture would become a progressive art, which could only be attained by pursuing it in a systematic manner. But as an aid towards that end it would be well if the services of architecture were more generally recognised.

Mr. J. Ely also responded.

"Literature," "The Visitors" and "The President Elect" were in succession toasted.

## THE HOSPEDALE MAGGIORE, MILAN.

TRAVELLERS from North Europe flow in great numbers at this season of the year through the St. Gothard Tunnel, writes a special correspondent of the *Glasgow Herald*, and descend with even greater speed than the melting Alpine snows to the warm and fertile valleys around Bellinzona, and to the borders of the blue Italian lakes. In Italy were founded the first medical schools, the first hospitals, the first human body was dissected, and the first surgical operation performed. The first modern hospital was built upon that spot in the seventh century; its special interest is that it was founded on behalf of Anglo-Saxon pilgrims. It was called the Hospital Spiritus in Sassia, in connection with which Pope Innocent III. organised from it as centre the hospitals of the Holy Spirit over the whole of the West. Of the old Tiber Hospital only two or three stones remain concealed among trailing brambles, and visible only when the Tiber is low. One stone has still upon it a graven serpent, symbolic of the healing art, and on another stone the ram's head is still visible, symbolic of wisdom, and representing the commonest offering employed in ancient times to avert illness and the consequences of sin—a symbol which has been associated with healing since long before the time of Abraham. These stones are the sole remnants of this first hospital. The so-called Hospices of the Middle Ages (especially of the early Middle Ages) were mainly intended to afford a short resting-place for pilgrims and travellers. The priests had barely time, however, to perform their prescribed religious routine, much less to assist the sufferers with remedies, or to inquire into the nature of their diseases. They thus, although they subsequently became hospitals, afforded little help to the sick or to medical science.

In this year of celebration, hospitals of this country are attracting a considerable share of public attention and public assistance, and one would naturally turn to this land of the first hospitals, towards the country which opened the gates of medical science to surrounding nations, to observe modern progress, to learn ancient secrets and obtain the fruit of ancient culture. The visitor to Italian hospitals, however, will be sadly disillusioned. It often happens, that ancient institutions rest upon their former splendour and achievements; improvements are slowly adopted, ancient rites, ceremonies, methods, apparatus and *personelle* retain in them their pristine forms. When to these factors is added the effect of the cloister and the convent, there is less cause for astonishment that the labour of the first years should have become less efficacious, and that the progress of science should latterly in those countries have come to be in some degree paralysed. The Hospedale Maggiore at Milan, the largest hospital in Italy, affords a terrible example of a Mediæval hospital existing in the midst of nineteenth-century requirements. Italian glamour without gives an imposing appearance and a gaudy air to this huge building, which has existed from the middle of the fifteenth century, its foundation being contemporary with the invention of the art of printing. Its outward form engaged the skill of Antonio Filarete of Florence, of Richini and of Bramante, who devoted their art mostly to form, to terra-cotta decoration and external ornamentation, without troubling much about the rules of hygienic hospital construction or the selection of a suitable hospital site. They erected a massive building on the banks of a half-empty, sluggish, smelling canal in a low, crowded, dull and dirty part of the town. The building resembles a huge prison, and strikes the visitor with a sense of pity for the inmates. It has twenty-eight large and gloomy wards, stone floors covered with dust, whitewashed walls bespattered with finger-marks and cobwebs, and many of the wards have the beds arranged in four rows. The sense is suffocated and the mind distressed with the odours of disease and the spurious sanctity which pervade all the wards. The surgical wards would excite much concern in the mind of Lord Lister, the operating theatre would accomplish the resignation of Professor M'Ewen, the arrangement

and style of instruments would excite contempt among dissecting-room caucuses, and the sight of the performance of minor surgical operations in the open wards would create a panic in the hearts of lady visitors accustomed, for instance, only to the healthy and cheerful look of the surgical wards of the Royal Infirmary of Glasgow. Milan, the birthplace of Langfranc, the founder of surgery in Europe, is perhaps the last place at which one would care to have a limb amputated or an open scalp wound dressed.

The medical wards are antique in type, form and hygiene. The marble floors look bleak and cold for the tottering feet of the stricken ones; the walls are bare, no piece of green foliage in the room; all desolation, as if to render the distressed a fitter prey to that sorrow which already presses upon them. Upon festival days the external appearance of this hospital is gay in the extreme. The religious bring their offerings to the priestly coffers and are duly besprinkled with a wet brush. Portraits of departed donors were exhibited around the arches, emblazoned with scarlet and gold; those of them who had bequeathed 100,000 francs or more were known from their portraits being painted in life-size; those who had left half that sum were done in half-size, and those who had given less were depicted according to the manner of their subscription in various degrees of artistic excellence down to the merest daub.

### THE GREEK THEATRE.

AT the Royal Institution, Albemarle Street, on Saturday, the Rev. Dr. J. P. Mahaffy, professor of ancient history in the University of Dublin, delivered the first of a course of three lectures on "The Greek Theatre according to Recent Discoveries." In his introductory remarks the lecturer said there was no part of the wonderful civilisation of the Greeks which had made a greater impression upon modern life than the drama as developed and perfected by them. If it were not certain that they actually discovered the form of literature it was certain that they dealt with it in such a way as to leave but little room for improvement in its essential features. He alluded to the absence of direct evidence on the subject of the Greek theatres, and said that the inferences to be drawn from the Greek plays were scanty and those from the Greek grammarians inconsistent. The theatres at Pompeii were, he supposed, by far the earliest excavated, but we had no certainty that these theatres were not Roman. It was not till 1862 that by the efforts of the German, Strack, the site of the theatre of Dionysus at Athens was cleared, and we found out what this famous structure was in the last stage of its development. The lecturer proceeded to describe his first visit to it early in the seventies, remarking that its curved rows of seats, the orchestra or flat centre, with its tessellated ornament, and the marble row of stalls around it, with the names of the official occupants, were unmistakable. There was something piquant in seeing the monumental evidence of the close connection of play-acting and religion; to see that what we might call the deans, canons and prebendaries at Athens had their stalls, not in the choir of a church or temple but in the front of a playhouse, where not only solemn tragedy but ribald comedy occupied the audience. The discoveries of other Greek theatres were next alluded to, and their ruins described with the aid of views thrown upon a screen. It was with these discoveries, he proceeded, that the comparative study of Greek theatres became possible, and it was to architects that we owed all our greatest discoveries in connection with them. There was good reason to believe that the Greeks, so great in sculpture and in architecture, were not great in music or in painting, and if nothing had been preserved in classical times but the music of the Greeks it would have been difficult to suspect their greatness in other fields. With regard to the plays, Æschylus, rude as he might have been in his scenery, made great advances upon his ruder predecessors.

### HISTORICAL EXHIBITIONS.

AT the opening of the exhibition of pictures and other objects illustrative of the Tudor dynasty which have been collected by a committee of the Manchester Art Gallery, the Duke of Devonshire spoke of the leading part taken by Manchester in the promotion of loan collections of art, beginning with the great example set at Old Trafford forty years ago. The Tudor exhibition was of a kind that must, not only from an artistic but from an historical point of view, lead to most instructive and interesting comparisons. Such an exhibition dispelled the popular fallacy and impression that history could only be learnt in books. It enabled men to better understand that which they could learn from books, and it made the knowledge more vital and gave life to the characters represented. When they saw the portraits of those who lived in bygone times and the pictures of the scenes in which they

acted, when they were brought into direct contact with the relics and mementoes of those times, they were put into touch with men and events, and the actors in those periods spoke to them directly, and not through the medium of the theories or prejudices of the literary historian. It was sometimes urged in these days that too much stress was laid by history upon the doings of princes and statesmen, and that the work of the scientific historian was rather to trace national development. The newest school of all would seek to attribute to economic causes much of that which had been found in religious or political movements. From that point of view it might appear that the division of our historical material into dynastic periods might be picturesque, but was somewhat unreal. On the other hand, he thought it was possible to hold, having regard, at all events, to our own history, that dynastic division was in the highest degree vital. Our Plantagenets, Tudors and Stuarts were more than actors; they were authors of the scenes in which they were actors. The Tudor period was one of the widening of learning both in the physical and intellectual world. Men at that period began to look with new eyes at much that had hitherto seemed fixed and immovable. The old order did not give place to the new without a struggle so long and so fierce and of such varying fortunes that in following its phases we were apt almost to forget the great principles and issues that were at stake. In the course of that struggle, as had generally been the case, much was lost and destroyed that might well have been spared. It was one of the advantages of the study of history from the view of contemporary movements and records such as that exhibition afforded that our tolerance extended as our knowledge and intelligence deepened and widened. When we heard almost the very voices of the men who acted in these scenes as they spoke to us in their idiom, strange to our modern ears, from the black-letter pages of their contemporary records, we could learn and understand something of the complexity and the difficulty of the circumstances in which they acted. We could learn how dark much must have appeared to them which now appeared to us as clear as day, how crooked were the roads which to us seemed so smooth and easy, how feeble and uncertain at times was the guidance which they could receive. When we looked at the history of the time in that light we should hesitate to pronounce that partial and hasty judgment on the action of those men which on imperfect knowledge it was too easy for us to form, we should accept with gratitude the results of their acts that they had bequeathed to us, and we should learn to understand much of that which we rejected, and should appreciate the difficulties of those who were not better able to forecast the future than we were ourselves.

### PHœNICIAN ART.

A LECTURE was delivered in the theatre of the Royal Dublin Society by Prof. Baldwin Brown on "Phœnician Art." He said the Phœnicians were known more in history as a roving, seafaring people, and it had been questioned whether they attained to anything of artistic importance. However, the theory that commercial development was incompatible with artistic excellence was refuted by the case of the Florentines and also of the Venetians, and scruples as to the artistic capacity of the Phœnicians were really set at nought by the account in the old writings of the works executed by them. The Phœnicians probably excelled any other of the old nations in producing grand effects in building by the use of very large materials. The biggest stones used in masonry were cut by their hands, and some of the stones used for the terraces on the Hill of Zion lay at the present day where they placed them. Some of these were 20 feet long by 3 feet in height, and remained there intact after the lapse of 3,000 years. From the accounts they had of their achievements, there could be no doubt of the artistic attainments of the Phœnicians. He then showed on the screen specimens of bas-reliefs and other types of Assyrian stone carving. The lecturer then turned to art as it existed in the early Greek age, and dealt with the recent discoveries on the site of the ancient Mycenæ. There was little, he said, of continuity between this older art and the later Greek art proper. Homer regarded the Phœnicians as holding the highest place in art in his age—800 or 900 B.C.—and appeared to regard the Greeks as copying from them. It had been said of Greek art proper that its groundwork was centred in the world of Olympus. About 650 B.C. the human form began to force itself in as a motive in their art, and soon became the preponderating feature. The commencement seemed to be in the shaping of figures in wood, and even in the second century before Christ they had the testimony of Pausanias that he had seen the remains of a wooden column. In conclusion, the lecturer showed types of early Greek vases and coins, and also views of the present site of Olympia, and the excavations carried on there by the German Government.

## NOTES AND COMMENTS.

THE remarkable success of "expanded metal" for fire-proof and various other purposes in building in this country is only a repetition of what occurred in America. The material seems to act like the web plate of a girder, and to convey for a time all the strains which come upon the structure of which it is a part. In its steadiness lies the safety, for the difference between the sustaining power of a wall, partition, or beam with expanded metal as a hearting, and one without that auxiliary, is surprising. According to the report of Sir JOHN FOWLER and Sir BENJAMIN BAKER, whose authority as engineers is unquestionable, "the use of expanded metal in the case of a 3-foot 6-inch span increases the strength of a flat concrete slab from six to eight times the strength for carrying a uniform load that it would have if made without the metal; and in the case of a 6-foot 6-inch span, the strength is increased to ten and eleven times." They also say:—"As regards strength, the slabs made without expanded metal did not approach those made with the metal, and that even with a neat cement slab the strength was much inferior." It would seem that the old experience of fitch beams is to be repeated in expanded metal slabs. There is security with the metal against the least approach to torsion, a sort of action which is much more common than is generally supposed, and to counter-balance it a mass of material is generally employed, which simply means the substitution of one inconvenience for another. The use of Mr. GOLDING's latticing or mesh work has given a new impetus to the demand for concrete, which is now applicable to purposes that were not foreseen half-a-dozen years ago. Full information concerning the material will be found in a little treatise issued by the Expanded Metal Company, Limited, which should be studied by every architect and builder in the country.

AMONG the additions to the section of ethnography in the Mayer Museum, Liverpool, is a facsimile of the "Codice Messicana Vaticano," presented by the Duc de LUBAT. It is one of a number of the ancient Mexican codices, executed at the expense of the duke, who has for many years taken the deepest interest in these Mexican antiquities, of which only a very few specimens have been preserved in some of the richer libraries. The Mayer Museum is fortunate in possessing an example of one of the finest originals of these books, which consist of ritual calendars, histories, and tribute rolls of the ancient Mexicans, written before the date of the discovery of America. The British Museum and the Bodleian Library are, it is believed, the only repositories in England, besides the Mayer Museum, of examples of these treasures, and on the Continent the chief are Paris, Rome, Dresden and Vienna. These codices are inscribed in hieroglyphics on pages made of pieces of deer skin of different sizes gummed together, having a white chalky composition spread over them, on which the curious pictures are drawn and painted in colours. To their interpretation we had, until recently, almost no clue. In 1895 Señor FRANCISCO DEL PASO Y TRONCOSO, the director of the National Museum of Mexico—a well-known scholar and authority on these documents—spent several weeks in studying and elucidating the Mayer codex, both in the Museum and at Oxford University, where the codex was, with the permission of the committee, lent to Señor TRONCOSO for several months for the purpose of enabling him to compare it with the codices in the Bodleian Library. In recognition of the committee's kindness Señor TRONCOSO gratuitously used his influence with his friend, the Duke of LUBAT, and induced him to present a copy of the Vatican codex 3,773 to the Mayer Museum. The reproduction of this codex is in absolute facsimile to the smallest minutiae of size, binding and coloration. Accompanying the codex is a small pamphlet (in Spanish and English) on "The Manuscripts of Anahuac," by Señor PASO Y TRONCOSO, giving an account of the "Nahua Book" (as the Vatican codex is called) and how it is to be read. The Duke of LUBAT, in presenting the facsimile, expresses, in a note addressed to the director, the hope that some of the rich merchants of Liverpool may be induced to provide the cost of producing a facsimile of the precious Mayer codex after the manner of the Vatican "Nahua Book."

## ILLUSTRATIONS.

## CATHEDRAL SERIES.—NORWICH: VIEW FROM SOUTH-EAST.

## THE EMPIRE PALACE OF VARIETIES, MIDDLESBROUGH, YORKS.

THIS Theatre of Varieties is immediately to be erected on one of the finest sites in the town, adjoining the Municipal Buildings in Corporation Road.

The site covers an area of 11,000 square feet, and is bounded on three sides by wide streets with a right of way in the rear, thus enabling an arrangement of approaches and exits in a most simple and complete form. The elevation itself practically discloses the principle of the planning, with its staircase towers at each angle leading from the circle and gallery. The main entrance to the stalls and dress-circle is in the centre, with saloon over. There are thirteen exits in all. The theatre is in two tiers and will accommodate 2,000 persons. Ample lounges and saloons are arranged, and particular attention has been devoted to the formation of convenient retiring-rooms and lavatory accommodation.

The dimensions of the auditorium proper are as follows:—Width, 60 feet; depth, 65 feet; height, 45 feet to sunburner.

The stage is 70 feet wide, 38 feet deep and 56 feet to the grid, giving ample space for spectacular sketches and ballets, and the dressing-rooms will be of the most convenient description.

A complete electric plant will be laid down for the lighting of the whole building by electricity. The building will be faced with terra-cotta of two tints, by Messrs. DOULTON, and the iron and steel-work will be by Messrs. DORMAN & LONG, of Middlesbrough. The hall will be opened about the end of the year. The original drawing is exhibited in the Royal Academy. Mr. ERNEST RÜNTZ is the architect.

## 5 QUEEN STREET, MAYFAIR. NEW DINING-ROOM FOR MR. CHARLES GRANT DUCROZ.

THIS room is panelled throughout with oak, having a velvet frieze above. It is lighted by a cupola and bay window, and approached through an inner hall of similar character.

This room and the general contract for other alterations was entrusted to Messrs. BRASS & SON. Mr. ERNEST RÜNTZ is the architect.

## THE BRITISH EMPIRE MUTUAL LIFE ASSURANCE COMPANY'S NEW BOARD-ROOM.

THIS room forms a part of the extensive alterations to the company's offices at 4 and 5 King William Street, London. It is situate in the basement, and light is admitted by a semicircular bulkhead cutting into and conforming to the design of the ceiling.

The whole of the room is in white enamelled panelling. The general offices have been completely revised and a great economy of space effected.

The general contract was entrusted to Messrs. SIMPSON & SONS, the hot-water engineering to Messrs. STRODE & Co., and the furniture and fittings to Messrs. DREW & CADMAN. Mr. ERNEST RÜNTZ is the architect.

We have been requested to announce that Mr. RÜNTZ has removed from 22 Moorgate Street to more commodious offices at 10, 11, and 12 Walbrook, E.C.

## THE ROYAL MUSIC HALL, HOLBORN.

WE illustrate the new terra-cotta façade to this well-known hall, necessitated by the enlargement of the approaches, increased saloon accommodation and the building of a restaurant and supper-rooms adjoining. The work is being carried out for Mr. JOHN BRILL, the proprietor, by Messrs. DREW & CADMAN, of High Holborn, the terra-cotta being supplied by DOULTON & Co., and the hot-water system by STRODE & Co. The works will be completed by Jubilee Day.

The original drawing is exhibited in the Royal Academy. Mr. ERNEST RÜNTZ is the architect.

The Architect, May 7<sup>th</sup> 1897.

## NORWICH CATHEDRAL.

ALTHOUGH Norwich Cathedral contains much work which is characteristic of the Norman period, and is classed among the oldest of the English buildings, it is well to remember that Norwich was not always the episcopal capital of East Anglia. In the seventh century King SIGEBERT persuaded a Burgundian monk named FELIX to come among the Angles as a missionary bishop, and his seat was set up in Dunwich. The king afterwards retired to the monastery of Bury. This gave PENDA of Mercia an opportunity to invade East Anglia, and during several years the country was subjected to all the misery he could inflict. SIGEBERT was at last induced to leave his cell, but it was too late to repel the invader. He and his son, who had succeeded him, were slain with many of his subjects. The position of FELIX during the wars was unenviable, but he contrived to hold his office for a term of seventeen years. He was succeeded by THOMAS BONIFACE, who was followed in 669 by Bishop BOSA. In his old days BOSA found he could not control the whole of East Anglia. Accordingly he arranged for its division into two dioceses. The cathedral of one of them remained at Dunwich, for the other North Elmham was selected as a site. In course of time the two divisions were reunited, and Elmham became the centre.

When WILLIAM of NORMANDY arrived, one of his cares was to make such a division of the country for ecclesiastical purposes as would be most advantageous to the interests of the invaders. In Elmham he placed one of his chaplains named HERFAST about the year 1070. But HERFAST was not satisfied with the accommodation, and seized on the abbey of Bury St. Edmunds, which he wished to convert into a cathedral and palace. The abbot, however, fled to Rome, and laid his case before the Pope, who decided in his favour. HERFAST would not surrender the abbey, and he was likely to have imagined he would gain the support of WILLIAM. But the Conqueror had too many ecclesiastical broils already awaiting settlement, and at a council in Winchester, which was held in 1081, he refused to recognise the claim of HERFAST to the abbey, and ordered its restoration to its former possessors. But the stubborn bishop, if defeated in one position, soon took up another. He could not hold Bury, but he declined to go back to Elmham. The bishop's seat was therefore removed to Thetford. HERFAST erected a cathedral and residence in that town, of which no remains have survived. When he died in 1085 he was succeeded by another of WILLIAM's chaplains, named GALSAGUS or BEAUFO, who held office for six years.

In 1091 HERBERT DE LOZINGA attained, or rather acquired, the bishopric. His name is more closely associated with the cathedral of Norwich than those of his successors, but he should not be judged by an apostolic nor by a later standard. HERBERT was a type of some bishops of his time who invested their money and their energy in the Church because they found an ecclesiastical office could become a most profitable speculation. He paid 1,900*l.* for the East Anglian bishopric and laid out 1,000*l.* in the purchase of an abbacy for his father. Such immense sums suggest how enormous were the revenues. But powerful as were the bishops, they could not act as they pleased. Intelligence of the purchase found its way to Rome, and HERBERT DE LOZINGA was summoned to appear before Pope URBAN II. to answer for his simony and various misdeeds. He was deprived of his crozier and other signs of authority. They were not restored to him until he had agreed to employ his wealth in the erection of churches and monasteries. He returned to England, and as a first step towards the performance of the penance laid on him he resolved to remove from Thetford to Norwich. In the year 1096 he began the foundations of the building which is now known as Norwich Cathedral, as well as a palace on the north side. Ten years afterwards a priory was founded by Bishop HERBERT. He died in 1119, having, according to BLOMEFIELD, erected the choir, transept, central tower and a part of the nave. His successor, EBORARD, is credited with the rest of the nave and aisles.

Although the Norman part is so plain in character, there is much difference of opinion about the extent of LOZINGA's work. Professor WILLIS was of opinion that it did not extend beyond four arches of the nave on the western side. One reason for his conclusion was that the mouldings of

the ante-choir were similar to those in the upper tier of the choir, and also to mouldings which are found in the Tower of London that was built by WILLIAM THE CONQUEROR. But it is supposed that those ancient mouldings have been tampered with, and are therefore less trustworthy for verifying dates than the Professor believed. The zigzag or chevron ornament, which is common on the more westerly part, was also supposed by Professor WILLIS, and other archæologists, to be an indication of a later period, but that circumstance is also controverted, for the chevron is found in eleventh-century work in Normandy. Some have also explained the peculiarity of the pair of massive cylindrical piers in the nave, which are covered with spirals, by suggesting that they indicate the boundary between LOZINGA's and EBORARD's work, but there is no evidence to support that theory.

It is remarkable that there should be two dates given for the commencement of the cathedral, viz. 1096 ("Norwicensis ecclesia fundata est"), and 1115 ("Fundamenta ecclesiæ Norwici"), and not one to record its completion. The next entry which has survived relates to a fire in 1171 ("Ecclesia Norwici comburitur"), and to the completion of restoration which came to an end in 1196 ("Joannes de Oxoniâ consummavit Ecclesiam ab Herberto inceptam et Infirmary ædificavit"). Whether Bishop JOHN followed his predecessors' work cannot be decided. But with the Norman race there was less of local variation than in later times. As the late J. D. SEDDING remarked:—

The first thing to note in this matter is, how much more akin the arts of the Northern races are in the early formative stage than in their formed stage—in their beginnings than in their endings. Starting from the common ground of the Romanesque, the various nations keep for a certain time in parallel lines. All their opening strokes are very similar in spirit and character, and when they begin to develop things the developments overlap one another, so that in passing from the early art of one people to the early art of another we get no sense of disconnected thought. Not that there is no real difference at the very first, but that the differences are not developed. The line of demarcation at starting is but as the separation of a narrow stream over which people can still touch hands; but as time goes on the banks widen, the lines of demarcation stretch indefinitely, so that by-and-by the points of contact have entirely disappeared.

If we allow for this similarity as a general characteristic of Norman, the difficulty of determining between the various works undertaken during the twelfth century at Norwich will be less incomprehensible. The next change was the addition of a lady chapel, which was erected by Bishop SUFFIELD between 1244 and 1257. It no longer exists. In 1271 the tower was injured by lightning, and in the following year the cathedral was partly wrecked in the course of a contest between the monks and the citizens. The repairs required six years to carry out. In 1278 the church was reconsecrated, a ceremony which we suppose was considered necessary to atone for the vandalism. Then in 1295 the spire was commenced, but it was not completed, apparently, until 1361. Another slow work was the erection of the cloisters. They were commenced at the end of the thirteenth century, but it was not until 1480 that they were ready for use. The spire was injured by lightning in 1463, but the damage was promptly repaired by Bishop LYART. It is supposed the great west window was erected by the same prelate. The stone vaulting of the choir is attributed to Bishop GOLDWELL and Bishop NIX. Several of the Norman windows were also transformed to be in keeping with the later additions, but in spite of all that was done the Norman work continues to be in the ascendant.

## THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Architectural Association was held on Friday last, April 30, Mr. Beresford Pite, president, in the chair.

Mr. Hugh Stannus discoursed on one of his analytical diversions, viz. the Classic cornice. Several diagrams were explained, but without copies of them it would be impossible to convey an exact notion of what was said. Mr. Stannus described in detail the elements of cornices, and offered suggestions about the dispositions which would enhance their effect. But he was particular in emphasising that the theory or gospel was his own; however, he did not recommend anybody

to accept it as infallible. Although the theory might not be accepted to-day it was not impossible, he thought, that hereafter it would be adopted in principle.

The President said it was a practical subject, but one which the student would find he had to grapple with sooner or later. As a rule, clients were not disposed to interfere with such details, but they appeared characteristic of the designer. Mr. Stannus was silent on the subject of a freehand treatment when designing a cornice, but it would be an advantage in many cases to neglect the use of compasses, and trust to the hand as directed by that instinct which Mr. Street used to eulogise. For curves the principal source was to be found in those belonging to the human body, but the archaic Greek curves were admirable exemplars of form. Much subtlety was lost in the transition to Roman contours. He hoped some use would be made of Mr. Stannus's advice, as there was need for the consideration of the intellectual aspects of architecture.

Messrs. Brodie, B. F. Fletcher, and Pratt also spoke.

Mr. Stannus, in reply, explained the immense labour which had to be undertaken by Alfred Stevens before he could satisfy himself about any form. In some cases at least 150 attempts had to be made. Owing to his fastidiousness they were not valued, although to other eyes they would have probably appeared beautiful. There is no royal road to the designing of mouldings, and he would advise the student to be unceasing in copying Greek as well as Mediæval examples. It must not be supposed that he advocated T-square and compass work. On all occasions he had persistently advocated the advantage of freehand treatment. There could be little doubt that the Greek mouldings were originally freehand drawings, although they were probably matured by some geometrical process.

There was an unusually limited attendance.

## SCIENCE, ART AND LITERATURE AT THE ACADEMY BANQUET.

THE annual banquet of the Royal Academy was held on Saturday evening under the presidency of Sir E. J. Poynter. In responding for "Science," Lord Kelvin said:—

When I look round this hall, and when I see the galleries of the Royal Academy, I see the splendid results of science everywhere. Every picture, every statue is truly a scientific work. I believe the scientific eye alone can thoroughly appreciate the splendid success of the work of the Royal Academy and of artists throughout the world. It seems incredible to a person looking at a picture closely, and examining the grain of the rough canvas, that when he turns away and looks at it from another aspect it should blaze out with light and beauty. Science takes the humble position of servant and helper to art. I think it must be admitted that science has contributed in no small measure to artistic development. What would Raphael and Michel Angelo and their great predecessors who for centuries laboured through the geometric art of perspective have thought if they had seen a photograph? Would they not have said, "This is a masterpiece of art?" I do not venture to suggest a comparison between the beauty of a photograph and the beauty of a painting; but I do say that if the inventors of the art of painting had seen a photograph they would have been delighted and astonished. I hope I do not offend when I say that artists do think that in some respects a humble photograph gives them ideas as to possibilities of treatment which, without that aid, might not have occurred to them. I do not venture upon a comparison, still less would I say that the last development of science in relation to art, the automatic photographing of colour, is for one moment to be put in competition with artists' work. I am quite sure, however, from the liberality of mind always displayed by artists, that they will thoroughly appreciate the scientific marvel which has thus been realised. Two modes of photographing automatically in colours have come to the front within the last two or three years. To the science of Thomas Young and others, who have worked at and improved and illustrated the true theory of the composition of colours, who have taught artists that yellow and blue do not make green, who have taught artists what green is, what red is and what the primary colours are, we owe that admirable and in so many ways interesting development in photography. I need not mention in an assemblage of artists, and of the admirers of the work of artists, that it is only a rough approximation to that which is achieved by artists, but I do say that, as a scientific result and an automatic production, these photographs in colour are worthy of great admiration. But there are still more marvellous developments of science which have produced splendid results. There is the working-out of the undulatory theory of light and of the analogy between vibrations of sound reflected back from a wall and of light reflected from a mirror. I am perfectly sure that all artists look upon these results with intense interest. Some of the most recent developments of science during the last two or three years have been in connection with the sub-

ject so interesting to artists—light. Light is the means by which we see paintings and sculptures, and the effects of light and shade give the colour which art wishes to produce. Surely, therefore, it will interest artists to think that light is produced by means of vibrations. Among recent scientific discoveries there are not only the Röntgen rays but the uranium rays—a piece of scientific witchcraft. I do not expect that artists will go into a dark cellar and paint pictures by the uranium light, or that they will ever take advantage of the Röntgen rays, which enable one to see through a substance; but artists will feel an interest in these discoveries in regard to other kinds of light because they themselves do their work by means of light.

Mr. Alfred Austin, in responding for "Literature," said:—Ever since the day when Dante stood by Giotto's side as he fixed on the frescoed wall of the Arena Chapel every act and scene of the Divine drama from Bethlehem to Calvary, literature has inspired some of the greatest pictures in the world; and as to-day one feasted one's gaze and refreshed one's spirit with the latest and living proofs of the genius of British art, over and over again one was reminded that literature shares with nature the proud distinction of being to painting the true Fountain of Jouvence, the perennial well-head of its periodically-renovated youth. Would it not be strange were it otherwise? I never knew the artist who was not a lover of literature, and not a few great painters have been at the same time great authors. The literature of the Renaissance would be sensibly poorer if one, expunged from it the sonnets of Michel Angelo and the brilliant speculations of Lionardo; and English art has, in this respect, followed faithfully in the footsteps of those great precursors. The earliest president of the Royal Academy, the great Sir Joshua, wrote a work that remains a classic. Its great president of the present generation, Leighton of the many tongues, the many gifts, would be remembered by his speeches and his essays, had he never drawn a line nor ever mixed a colour. His successor, his too brief successor, dear genial Millais, whom we all loved even more, if possible, than we admired, maintained, it is true, a more concentrated, a more exclusive devotion to his fascinating vocation. But I never met the man more quick to appreciate or more eager to extol whatever verse seemed to him to have caught something of the music of the mountain stream, something of the colour of the mountain heather. Painters were the first to feel the magic of the poetry of Keats, the first to discover and proclaim the interpenetrating charm and finished felicity of Tennyson. And were anyone to assert that, thanks to a certain keen but disinterested sympathy, artists are the soundest and surest judges of the higher literature of their time, I should not be tempted to contradict him. There is thus a tie, there subsists a bond of kinship, between literature and art, compared with which this, your annual communion with principalities and powers, however natural and pleasing, seems fortuitous and transitory.

The President next proposed "Our Guests." He said:—I have already had the honour of welcoming by name, in the various special toasts which I have proposed, some among the many distinguished guests who have honoured us with their presence on this occasion. We are able to boast that besides these we have here gathered together representatives of most that is famous in every branch of life. Besides our royal guests, besides our sailors and warriors and statesmen, and those representatives of science, literature and commerce to whose interests and welfare we have already drunk, we have those distinguished envoys of foreign countries who come to us with the pleasant desire to reconcile rivalries and soothe jealousies, and among these, though we are unfortunate enough to be deprived of the presence of the recently arrived American Ambassador in his place at this high table, I am happy in having been able to secure Mr. Bayard's welcome presence before his departure from this country; we have the eminent men who represent to us our Empire abroad, the agents for our great colonies; we have dignitaries of the Church, statesmen of both parties, members of that great body of country gentlemen who contribute so largely to form the best of English social life, the owners of pictures, a class so indispensable to us as artists; and we have distinguished musicians, and our most representative actor—all brought together here through their common interest in the most widely appealing of all the arts, all of whom we are proud to welcome, and to whose health and welfare and continued success in their various walks in life I and my colleagues drink in this last toast of "Our Guests," which I now propose, and with which I am permitted to associate the name of the right reverend prelate whose recent translation to the See of Canterbury has given such eminent and widespread satisfaction.

The Archbishop of Canterbury, in proposing the health of the "President of the Royal Academy," said:—Painting is a very wonderful art, because it gives a peculiar kind of pleasure, greater it seems to me than can be derived in almost any other way, and a pleasure at the same time of the highest and purest kind. It has been said that of all the pleasures a man can enjoy there are few indeed that can be compared with the pleasure that is obtained by some new idea or thought of beauty,

or some new thought of truth; and of all the means that can be employed to give that pleasure to men the art which is cultivated by the Royal Academy stands in the very forefront. We have every one of us heard it said that art should be true to nature; it ought to be unquestionably, and there is no condemnation of art so great as that which declares that it is false to nature. But at the same time the truth to nature is of a very peculiar character. What is it that I see when I look at a beautiful landscape-painting? Do I simply see the same thing that I see when I look at the landscape itself? Do I with my eyes see that landscape as the painter sees it? What pleasure is greater than to perceive through the inspiration of the painter that which makes the scene at the same time new and true? There is, we are told, "a light that never was on sea or land," and this, which the ordinary man cannot see, is very often revealed by the painter. The painter depicts not only what the ordinary man sees when he looks at the scene, but something more, and his picture tells a tale which is not told to ordinary eyes by the original scene. There is in every true work of art this kind of inspiration. I believe that the world is the better for having received it, and I believe that there is hardly any pleasure that can be compared to the pleasure we so derive. It is in the capacity of one who derives that pleasure that I would thank all the artists who have invited us here to-night, and I would ask you to join with me, artists and guests alike, in drinking the health of the "Royal Academy," coupled with the name of the President.

The President said:—I must express how deeply I feel the honour which has been bestowed upon me by the choice of my colleagues in electing me head of this great and ancient institution, now in the 129th year of its existence. Since its foundation many distinguished men have occupied this position and have passed away leaving a noble record of well-spent lives and work achieved. But they have, so to speak, generally worked out their destiny, and their task has been accomplished before the end of their lives has come. No such calamity has ever befallen the Academy as the loss of the two great men who died in the past year, each in the fulness of his powers as a painter, and each, one may almost say, in the fulness of his vital powers, for disease and not decay carried them off. In each case strength and death had a battle—terribly brief with the one, painfully long with the other; but with them it was not as with Alcestis, for whom Hercules struggled with Death and strength came off the victor—Death overcame, and the English school was deprived of almost one blow of the two most distinguished artists of the last half-century—of its greatest painter and of its greatest president. I have said within these walls at the distribution of prizes shortly after my election as president what I had to say of the position which these two men, each supreme in his way, held in English art; and, though I could say much more, this is not the occasion to dwell on a subject which will only renew the painful sense of void left in the hearts of the public and of their many affectionate friends. Of that wonderful exhibition held last winter of Leighton's life-work it is needless now to speak, as it is fresh in all our minds. Next year we propose to do a like honour to the memory of Sir John Millais. As we all know, this anniversary dinner was omitted last year. The lapse of two years sees many changes, and since we last met this Academy has lost, besides our two presidents, four of its members—Armitage, Richmond, Hodgson (our librarian, a fellow-student of mine in early days at Leigh's), and Henry Moore; and of the many who have disappeared outside our ranks, four, distinguished above the others, are worthy of a special word of regret—Alfred Hunt, one of the most refined of our landscape-painters; Albert Moore, a brother of Henry, our deceased member, the third of that remarkable family of artists of whom all three are now dead; William Morris; and my earliest friend, and beloved by every one who knew him, the brilliant and popular George du Maurier. Our exhibitions will be the poorer for the absence of their works. This is a year of exhibitions. They abound everywhere, both at home, where every section of the community is putting forth its full strength to honour the second jubilee of our gracious Queen, and abroad also, where there seems to be an international exhibition in almost every capital. At Brussels, particularly, where an unusual effort was being made by foreign countries to make a display of strength, I thought it right that the English school should be seen to as great advantage as possible. Encouraged by the liberal grant from the Government towards the expenses, and assisted by an energetic fine art committee, I was able to get together a nearly complete representative collection of English pictures and other works of art; and through the indefatigable zeal of all concerned our section was completely ready and open to the public on Saturday last, the day announced for the opening ceremony—which ceremony has, however, been postponed through the general unreadiness of much of the exhibition. I take this occasion to thank most cordially those gentlemen who have so generously assisted us, whether with money or by lending us the pictures by which our school is so well represented. Others who have important collections and could not

see their way to help us on this occasion, may, let us hope, be reserving themselves for the great exhibition to be held in Paris in 1900. If they can then spare some of their treasures, we shall have nothing to fear in the great competition which will then take place. This year, already famous in the annals of art by that magnificent bequest to the nation of the Wallace collection, will witness the completion of another most munificent contribution of examples of English art, in the splendid building which Mr. Tate has raised on the Embankment to contain not only the collection of pictures which he himself has made, and with which he has so generously endowed the country, but which with far-seeing liberality he has made sufficiently extensive to contain a national gallery of British art, a gallery which will be under the Trustees of the National Gallery, and so form an integral part of it, and which I hope will be to the gallery in Trafalgar Square what the Luxembourg in Paris is to the Louvre. Besides Mr. Tate's own pictures, the collection purchased by this Academy under the Chantrey bequest will probably be housed there, and a certain proportion of the English pictures in Trafalgar Square may also be transferred to it. Those who have seen the galleries agree that they are admirably adapted for their purpose; and they well may be, for Mr. Tate has spared neither trouble nor expense in making them perfect in every respect by the adoption of every modern improvement. His Royal Highness the Prince of Wales has consented, with a graceful concession to Mr. Tate's wishes, to open the galleries and make over this splendid gift to the nation some time in the month of July. There are many other matters of interest on which I might touch, but I am sure that you will be glad that I should conclude, as is appropriate, with my heartfelt thanks for the kind indulgence with which you have listened to me, and for honouring us with your presence to-night.

## THE FORMAL AND INFORMAL IN ARCHITECTURE.

(Concluded from last week.)

WE have now pursued, we think, the philosophy of the subject pretty nearly to its limits, and if correctly, how false must be the supposition of those who would limit the perception of the picturesque to modern times, and deny it any place in the minds and the feelings of those ancients of Greece and Rome who have generally been looked up to in matters of intellect and taste as unapproachable models. To trace up the picturesque to an elementary principle of the intellect is virtually to assert the impossibility of its being thus limited. Who in point of fact can imagine, we will not say an Apelles, a Praxiteles, or a Phidias, not the author of the Belvidere Apollo, or the Medicean Venus, not that Homer, who could so vividly paint the scudding of a storm, or the moonlight upon the crags, or the wave gathering in the distance, and coming in and bursting on the shore—not any one of the great authors in poetry whose names are famous, but even any ordinary contemporary of theirs, with common taste and refinement, looking at a regular landscape composition of the present day by Claude or Turner, and not appreciating its beauty; or surveying, we will say, without pleasure the broken arches, the ivy-mantled columns and the half-shattered tracery of the windows of Tintern Abbey, or wandering "siccis oculis" along the Rhine, with no feeling for the charm of the conformation of those piles of Mediæval masonry on its banks, so regular at once and so irregular; so symmetrical, yet so relieved from formality in their fantastic accumulation of turret, or battlement, or pinnacle, on side or summit, that they have all the picturesqueness of the ruin without being such?

However, we may suppose an objector to be still unsatisfied, and his difficulty to proceed from a comparison which we may conceive him to institute between the classical temple and its proper correlative in modern times, the Gothic cathedral. He may point to the spires and to the towers, to the innumerable pinnacles, the flying buttresses, the pointed arches, the traceried windows, the quaint carvings, the deep porches and the clustering columns of Amiens or Strasburg, of Cologne or Milan, and pronounce the Gothic to be decidedly on the whole a picturesque architecture—picturesque according to the strict definition we have ourselves given, and commending itself in point of fact, to the artist, as something ready made to his hand if he wants a subject, without the absolute need of alterations for that purpose, such as we found to be necessary in the case of the Greek temple. If the Gothic architecture, then, he may argue, is picturesque, and the Classic unpicturesque, here is manifestly a phenomenon, which, notwithstanding all that we have hitherto said, has still to be accounted for; nay, which may safely be asserted to betoken some radical difference after all in the intellectual constitution of the originators of the two

architectures; for here he may naturally remind himself of the German distinction between the Classic and the Romantic, the inventors of which have ever specially appealed to the broad differences characteristic of the two architectures in question, as substantiating the distinction; and, though we are not sufficiently at home in the literature of the "romantic" controversy to know whether it has been done, we suppose that nothing would be more plausible at first sight than to press the picturesque into the controversy on the romantic side. But a little consideration will show that the difficulty is not so serious that we need be driven to any unsatisfactory theory of this kind in order to escape it.

It may seem a contradiction, then, to say it, but the truth is that the Greek architecture which we have been considering as formal owes the whole of its beauty nevertheless to the picturesque principle. But our meaning will be understood if the conclusion be remembered which was drawn when discussing the ruin; we then saw that the perfectly picturesque was as nearly as possible the equilibrium of the formal and the informal. For, this being the case, it will of course follow that every variety of gradation is possible from the formal onwards to the informal till we realise that equilibrium. Thus, if the ruin—to return to our illustration—be but partially carried out, the result will be something formal in the main, but with a tendency to the picturesque; if carried further, yet not sufficiently far, it will then be picturesque in the main, but with a tendency to the formal. Just in the same way, then, as the Greek temple, when decay first begins to operate upon it, is a degree more picturesque than it was when quite perfect, so, we say, is the perfect temple itself a degree more picturesque than it would be were it quite formal; or, in other words, in so far as it is not the perfection of formality, so far is it picturesque. Now it is certainly not the perfection of formality, for, were it such, then the pediment, being a triangle, should be equilateral, which it is not (for, the base of it being larger in every case than the two sides, it is an obtuse-angled isosceles); and the rest of the façade, that is, the parallelogram on which the pediment rests, should in like manner be a square, which it is not, the leading lines of the Greek architecture being horizontal, or, in other words, the width of the parallelogram being, as a general rule, greater than the height of it. In like manner, a more perfect formality would be obtained by the substitution of four-sided for round columns, or again of columns absolutely round like a ruler, instead of tapering upwards, as they do in the best architecture towards the capitals. Now as to the pediment, the isosceles triangle of which it consists was adopted by us above as the very symbol of picturesque beauty, on the ground of its being the simplest possible exhibition in lines of a disturbed symmetry, and as to the parallelogram supporting this pediment, it will be easy to point out that it is precisely the same sort of exhibition of the picturesque in four lines which the isosceles is in three. What is it that we admire in a fine specimen of this part of the façade, for example, in the portico (to take the first instance presenting itself) of the Pantheon at Rome, which is an oblong parallelogram of the kind here referred to?

We say of it that its proportions are admirable. Let us ask, then, exactly what is meant by this word "proportion." Now we have seen it stated that it is a common thing for an architect who would have a room in a house which he is planning well proportioned to secure his object by the following empirical rule:—He draws any square A B C D, as in the diagram annexed; produces the two sides A B and C D indefinitely to E and F; draws the diagonal B C; from C F cuts off C G equal to this diagonal; through G draws G H parallel to A C, and in the parallelogram A C G H has produced a figure the proportions of which satisfy the eye and answer his purpose; whereas any perceptible departure from this form, whether by protracting or reducing the length of the parallelogram here drawn, will, so far as the effect is concerned, distinctly injure it. What, then, is the explanation of what we call in this particular case a good proportion?

The word "proportion" might tempt us at first sight to imagine that there is some discernible harmony or correspondence, properly so called, between the longer and the shorter of the four sides of the parallelogram, as there manifestly is between the two pairs of sides opposite to each other. Yet not only is there no such correspondence at all, but even the charm of the effect is actually due to there being none, as a mathematician will at once see on considering the figure; for it being a mathematical truth that the diagonal of a square is incommensurate with the side of it, it follows that the longer side of the parallelogram (C G) being equal by con-

struction to the diagonal C B of the square of A C is also incommensurate with the shorter side, which is A C.

Now the above is the analysis of the entire front of the Pantheon below the pediment, and there remains a parallelogram of the kind just described, which itself is divided by pillars into a series of intercolumniations, consisting of minor parallelograms of the same character, at right angles to the main one. The comment, then, suggesting itself on the observation of these facts is the following:—Here is exactly, it would seem, the same sort of effect produced by the four lines forming the sides of the parallelogram which is produced by the three sides forming the sides of the isosceles triangle, which is the pediment above the parallelogram. Both the one and the other is an example of "disturbed symmetry." The parallelogram that is exhibits, as does the triangle, the combination of a certain correspondence with a certain discordance, the correspondence being displayed in the accurate equality of the sides parallel to each other, and the discordance in the disparity of the two sides touching each other, which in fact are mathematically incommensurate, as just said. On the other hand, had the parallelogram of the façade been so lengthened that the two longer of its sides should have been exactly the double of the two shorter, a harmony or common measure would have been then created between the two, but at the same time the "proportions," so admirable at present, would have been destroyed by the process.

Remaining true, therefore, as it does, that the Greek architecture, speaking broadly and generally, is decidedly of the formal kind, and non-picturesque in consequence of so being, still it would not be what it is were it not for the picturesque principle. It is formal because the preponderating effect is on the side of formality. Thus the parallelogram just considered is absolutely formal so far as this, that it is composed wholly of straight lines, is divided into its component parallelograms by straight lines, that these lines are all of them arranged on a system of parallelism, that all which are parallel are also equal, and that the angles contained in the figure are all right angles. In all this, we say, the symmetry is so complete, and the effect thereof so formal, that the disturbance of this symmetry in the particular instance of the disproportion between the two sides touching each other in every parallelogram is insufficient to establish the balance on the picturesque side.

The Greeks and Romans, then, undoubtedly understood and appreciated the picturesque principle, since they used it to give the crowning perfection to a formal architecture; and the Gothic architect, in point of fact, did nothing more than develop this particular element, already germinant in the Classic, in like manner as he developed the simple colonnade and area of the Roman basilica into the multiplicity of pillars and redundancy of aisle and cloister of his own cathedral. This will be perceived, however, more distinctly if we consider for a moment the leading facts of the history of the formation of this architecture.

"Domus Jacob de populo barbaro;" the "Gospel palaces" came originally, there is no doubt, from Egypt, for from Egypt it was that their beginnings, the colonnade and the columnar temple, such as are to be seen amid the ruins of Thebes at the present day, were introduced into Greece; from Greece, where they underwent great modifications, they were transplanted to Rome and there further modified; and the final alterations which they received afterwards from the architects of the north produced Gothic. It is also notorious that the main element in that vitality by which the hall of Ozymandias developed in the progress of centuries into Cologne Cathedral, was the Roman addition of the semicircular arch to the Greek column.

Now, this addition was one especially calculated to assist the development of the new architecture in the picturesque direction. First, the place of the arch was above the intercolumnar parallelogram, which became, in consequence, to a certain amount less formal—that is, more picturesque, than it was previously. And further, as it so happened that this addition gave it an extension of form upwards, there followed, in due course, both the general substitution of the upward or vertical line for the horizontal, as the dominant one in the new architecture, whence the after-development of tower, pinnacle and spire; and there followed, in particular, that sharpening of the arch itself, hitherto semicircular, which was the culminating and crowning effect of Gothic development.

If we ask ourselves, then, the question, Why is the pointed arch so superior, as all acknowledge it to be, in this particular architecture, to any other variety of it; why is it the most especially Gothic of Gothic features; why is it so perfectly in keeping with the rest of the building? we shall find that what we have called the principle of the picturesque will supply the answer. The excellence of the pointed arch lies in its ministering to the expression of those two elements of sameness and difference which are the essence of the picturesque, and this, alike if we consider it in relation to the rest of the architecture, or as taken by itself. In relation to the rest of architecture, it is picturesque, because while in its sharpness and verticalness it is in harmony with the points, the pinnacles, the spires and, in a word, the upward convergence of the whole building, it

temper at the same time with a softening operation like that of the sun on winter frost-work, the angular rigidity of these masses, by the beautiful contrast of the flow of its own curves. Again, of itself, and independently of its position, it is picturesque also, for while there is symmetry in the two curves composing it—absolute symmetry, in so far as they are the counterparts of each other—there is also disturbance of symmetry in the fact that, proceeding as they do, either of them, from a different centre, they are each broken by the other at the point of collision. It is the semicircle with its centre cut out and the two sides approximated; and accordingly, while in the semicircle we perceive absolute uniformity and undisturbed harmony, the eye following its curve uninterruptedly from end to end, in the pointed arch, on the contrary, the sweep of the compass leads us inevitably away from the arch when we have followed half of it; whence we perceive it to be composed not of one curve but of two, and these both of them incomplete because antagonistic.

The pointed arch, then, being confessedly the special and representative feature in Gothic architecture, and being also, as we have now shown, the very sum and embodiment in itself of the picturesque principle, we may securely, we think, assume that the true key to the general analysis of the effect of that architectural system in all its parts is the principle in question; the same principle, as we have said, being the basis also of the combination of forms in the Greek system, but developed, owing to the invention of the arch, in a more abundant material, with more variety, and to a certain extent, in greater perfection, in the instance of the Gothic.

### PICTURE EXHIBITIONS.

ON Monday a free exhibition of pictures in the Stratford Town Hall was opened by Sir Henry Irving. In declaring the exhibition open the speaker expressed his pleasure at being permitted to take part in that ceremonial and to offer them his heartiest congratulations on the opening of such an exhibition. With the beautiful pictures he saw around him he had a profound sympathy, for they were like strolling players. He understood that they had already fulfilled a successful engagement in another part of the great borough of West Ham—at Canning Town—and he felt sure they would play at Stratford to full houses. In looking over some interesting figures he found that a similar exhibition there two years ago drew a total of 146,000 visitors in eighteen days. That was extremely impressive to a theatrical manager. They must excuse him if for a moment his mind was distracted by a vision of an average attendance of 8,000 playgoers at every one of his performances. He could not sufficiently admire the public spirit with which the people of West Ham had rallied to these exhibitions. It showed, amongst other things, how a work undertaken by their municipal corporation for the purely artistic pleasure and enlightenment of that community might excite an enthusiasm which, he was told, did not always reward the labours of corporations. That was an excellent augury. Twenty years ago there must have been citizens of West Ham who would have greeted with graphic expressions of incredulity a prophecy of the public work which had been there achieved during the last seven years. What was the record? He had a list of institutions, either completed or in progress, which had grown up amongst them in that period, including a public hall, free libraries, two recreation grounds, public baths, and they were rapidly extending the means and opportunities of rational and aesthetic recreation. These pictures had already enlarged the horizon of many minds. They had done incalculable good by giving impressions of beauty to men and women who toiled amidst conditions not always helpful to conceptions of the beautiful. They were true missionaries of civilisation, ministering to that eternal need of the ideal which was as instinctive in them as the craving for material happiness. The bane of congested life in great cities was the stunting of imagination, and it was for the culture of that precious faculty that the painter's art had so high a function. It was once a reproach that our social reformers laid so little stress on the value of this co-operation. There had been a pretty hard struggle to obtain the national recognition of the duty of opening art galleries and museums on the one day of the week which afforded unrestricted rest and leisure. They might congratulate themselves that no lingering prejudice could curtail the public enjoyment of their exhibition by treating nature and the artistic representations of nature as if they were doomed by original sin to turn their faces to the wall on Sunday. He supposed those pictures, after a while, would journey elsewhere, and he should be glad to think that they would be followed by equally distinguished vagrants. That would make a useful circulation of ideas, especially as it was not possible for everybody in West Ham to travel in search of the picturesque. Such an exhibition as the present

one did honour to the borough; it reflected the greatest credit on all those who had laboured for it as an expression of civic life and duty, and it gave infinite pleasure to a man like himself, whose busy moments were identified with the art of pictorial delineation, and whose leisure moments could not be better employed than in applauding similar endeavours in a kindred sphere. He thanked them for their kind reception, and had the greatest pleasure in declaring the exhibition open.

Mr. P. Alden expressed the hope that in time so populous a district as West Ham would be provided with a permanent picture gallery. The necessity for it was undoubted, as the population of the borough was now 271,000, and it was increasing at the rate of 10,000 a year.

### GOTHIC ARCHITECTURE IN NORTHERN ITALY.\*

TO understand Gothic architecture as practised in Northern Italy during the thirteenth and fourteenth centuries, and to be able to judge of its successes and failures when compared with the architecture of the same period as practised north of the Alps, it is essential that we understand the architectural environment of the Italian people.

As early as the latter half of the seventh century a style of architecture made its appearance at Pavia and elsewhere, in which features of construction and design mark it as distinct from the debased Roman architecture previously practised.

Owing to the disturbed condition of the country during the dark ages the new style made little progress, and it was not until the eleventh century that buildings of importance in the style were erected, but during the eleventh and twelfth centuries it held complete sway in every part of Northern Italy except in Venice, which from its insulated position and intimate commercial intercourse with Constantinople, sought its architectural inspiration from the east rather than from the west.

One other exception to the universal practice of the style is the church of San Miniato, in Florence, and in some other buildings in that locality, where we find a return to a more Classical style.

As this style was the immediate predecessor of the Gothic, and as some of its features were adopted by the Gothic architects, it will assist us in our study of the Gothic style of Italy if we briefly glance at some of its more prominent characteristics.

Before the advent of the Gothic style all the architecture practised, not only in Northern Italy but also north of the Alps, was characterised by the use of the round or semicircular arch, but though this important feature was common to the architecture of Italy, France, Germany, England and Scotland, each country employed it in such manner and in conjunction with other features as to give to it more or less of a national character. The national character of this round-arched architecture, while strongly marked, particularly in Germany and England, was, if possible, more marked in Italy, where it was practised in a style entirely different from the contemporary style as found on the north of the Alps.

The round-arched style which prevailed throughout Northern Italy before the introduction of the pointed arch is known as Lombard architecture, not that the Lombards who had established themselves in the land about the end of the sixth century had any architecture or produced any style of their own. They were, however, great builders, and there is little doubt that in the erection of their earlier buildings they employed native workmen who, knowing no other style than debased Roman architecture, would work in that style; but gradually under Lombard influence new features were introduced which in course of time produced the style to which their name is given.

During their sway, which extended over a period of about two centuries, the land was studded with churches and baptisteries erected under the auspices of their kings and queens.

Nearly all the buildings erected by them during the seventh and eighth centuries have disappeared; a few, however, remain as examples of their work, the more notable being San Michele of Pavia, San Frediano of Lucca and Sant' Ambrogio of Milan.

The Baptistry of Florence, it is claimed, was erected during the Lombard dynasty, but if this was the case it does not possess the characteristics of the style that marks the buildings I have named.

From the few examples of the early Lombard style which remain to the present day we can see the change in the proportions of columns and piers; the introduction of wild and grotesque imagery in their ornamentation of capitals and walls that mark the style as distinct from the Roman.

\* A paper by Mr. A. C. Hutchison, read before the Canadian Association of Architects.

During the two centuries which followed the rule of the Lombards Italy was in such a disturbed and unsettled condition that little or no progress in art was made, the erection of churches ceased, and only buildings required for defence were undertaken. In Venice, towards the end of the tenth century, the erection of the well-known St. Mark's was begun. Owing to the intimate commercial relations with the east, Greek architects were employed, with the result that in this city of the sea we have an independent development in architecture of a complex character that marks it as distinct from that of Italy.

As the development of the early architecture of Venice is foreign to my subject I will pass it by, and, returning to the mainland, we find that the darkness which had enveloped the land during the ninth and tenth centuries began to break and give place to a new era of activity in building. During the eleventh and twelfth centuries a number of buildings were erected superior in size and skill in construction to any that were built during the time of the Lombard rule. These buildings are marked by the leading features which characterised the early Lombard buildings, but in addition we find new features introduced that gave the style a step in advance and prepared it for the advent of the Gothic.

An examination of the work of this period will show that the uncouth and grotesque carvings which characterised the early Lombard buildings has given place to figures and groups in low relief of somewhat better workmanship but still crude in design.

The most conspicuous feature that marks the buildings of this period is one that stamps the Italian character upon the round-arched style as practised in Italy, and serving to separate it distinctly from the contemporary architecture north of the Alps. This distinctive feature of Italian buildings was the piling of tier upon tier of decorated arches differing from each other in design, and occupying the whole façade of the building to its very summit. The most notable examples of this arrangement are to be found in the churches of Lucca, but one that is better known to most travellers is the façade of the Duomo of Pisa.

Another feature introduced at this period, which always found favour with the Italians and which they continued to practise during the whole of the Gothic period, was the use of material of different colours in the construction of the walls and piers; sometimes it was applied to the outside of the building, sometimes to the inside and sometimes to both outside and inside. Usually the polychromatic effect sought for was obtained by the use of marbles or stones of different colours arranged in alternate courses.

I might mention other features that characterised the later Lombard buildings, and which, adopted by the Gothic architects, influenced them in their designs. These features I will be better able to describe when the views of the buildings are projected on the screen. It was not until the first quarter of the thirteenth century had passed away that the Pointed or Gothic style made its appearance in Italy, and when it did make its appearance in the first building erected in the new style—that of San Francisco at Assisi—we find it complete in its forms and details as then practised in the north. It appears that when the erection of the building to receive the mortal remains of the great St. Francis was determined upon, there was no architect of celebrity in Italy, and Elias, the favourite disciple of St. Francis, to whom the work was entrusted, obtained the assistance of a German architect named Jacobus. It was only natural that he should recommend and use the style of architecture then practised in his own country, with the result that in the crypt and in the interior of the upper church we have a style of architecture quite distinct from anything that preceded it in Italy. It is true that long before this time the pointed form of arch was frequently used as a constructive feature in the architecture of Sicily; its use there was no doubt owing to the influence of Saracenic art, which, along with Byzantine and Norman architecture, produced a strange combination that gives so much interest to the Mediæval buildings of that island. Though the pointed arch was thus used in Sicily, it did not in any way affect the architecture of Northern Italy; as I have already shown, it was introduced from north of the Alps. As soon, however, as it obtained a footing in Italy it supplanted the earlier round-arched styles, and the Italian architects were obliged to conform to the new style.

From the fact that it was an importation from a foreign country and was in a sense imposed upon the Italians, whose love for the round-arched styles was deeply rooted, it follows that we cannot in Italian buildings trace the gradual development from the round to the pointed arch as we can in France and Germany, and more particularly in England, where in many buildings we may mark the first use of the pointed arch in conjunction with the round arch. The struggle for supremacy between the old round arch and the new pointed arch in England was protracted, with the result that between Norman architecture characterised by the use of the round arch and the massive proportions of its piers and arches, and the Early

English period when the pointed style was supreme, we have a well defined transitional period that affords a most interesting study.

In Italian architecture there is no such transition period; when the Gothic was introduced it at once supplanted the Lombard style, and though the Italian architects never hesitated to use the round arch in connection with the pointed when it suited their purpose to do so, there is no building that I know of in which the change from one style to the other is defined as it is in buildings in the north.

As already remarked, Gothic architecture was an importation. The pointed arch, which is the basis of the style, was not an Italian invention, and though used by them, the possibilities of its use (except in a few buildings) were not developed as we find in the buildings of the north. This is not to be wondered at when we consider the environment of the architects of the Gothic period in Italy—on all hands they were surrounded by the remains of Roman architecture, with the result that Classic thought and design was never dead, but only slept, and was ever ready to assert itself in some feature or design, or in the appropriation of ready-made materials of ancient buildings.

The designers of the cathedrals north of the Alps were under no such influence; they knew nothing of Classic art, and pursued the practice of the Gothic, working on without a suspicion that any other style existed.

As an illustration of this, I remember some years ago examining some fine old glass in Lichfield Cathedral. In one of the panels there was a representation of the building of Solomon's temple. In this picture the temple is shown as a great Gothic cathedral, the artists who designed it probably never suspecting that it might have been in another style.

The vital principle of Classic architecture is horizontal, that of Gothic is vertical. One is that of the column and lintel, involving the idea of rest; the other is that of the arch, the flying buttress and pinnacle, involving the idea of life and motion.

The two ideas are directly opposed to each other: the moment Classic architecture admits the arch it ceases to be true to itself in any real artistic sense; on the other hand, if it refuses to use the arch it confines itself within limitations of construction.

Unfettered by any classical restraint the architects of the north carried the use of the pointed arch to its highest perfections, and in their great cathedrals have left us examples of skill in scientific and artistic construction which, though often imitated, have never been surpassed.

Italian architects, on the other hand, were always under restraint, and while forced by the fashion of the time to use the pointed form of arch, they were never able, except in a few instances, to do so with the boldness and skill of their contemporaries of the north. They often employed it for mere ornament, and in many instances in so faulty a manner that the arches had to be held together with iron ties from the day of construction.

While the Italians here failed to produce buildings in the Gothic style in the purity of design and skill in construction that are to be found in the north, they have, nevertheless, executed many noble buildings in which we can study their successes and failures in dealing with a style that was not indigenous to the country, and in which they endeavoured to reconcile the principles of two styles that are far apart, and which we are inclined to consider unreconcilable.

Besides the influences to which I have already referred, there are other two which we find more or less strongly marked in Mediæval work: these are first, local, and second, personal influences.

Local influence was a natural result of the division of the Italian people into two hostile camps of the Guelphs and Ghibellines; the adherence to one faction or the other not only kept the cities apart, but often at war one with the other. When we consider the disturbed condition the country was in, in consequence of these quarrels, we might expect to find art retarded and incapable of development; on the contrary, however, we find that progress was made, but owing to the lack of community and freedom of intercourse the principal cities developed the Lombard and Gothic styles of architecture in a manner peculiar to themselves. Thus we have well-defined local characteristics of the Lombard style at Pisa and neighbourhood, and of the Gothic style in Venice, Verona, Bologna, Florence, &c. These cities, along with others which might be named, became at a later date local centres or schools of painting, each marked by treatment of their subjects peculiar to the great masters of the respective schools. We thus have in the domain of the fine arts the Venetian, Florentine, Pisan, Milanese and other schools, and in like manner we have the local characteristics of the respective cities marked in their architecture.

The personal influence exerted by individual architects is more marked in Italian buildings than in those north of the Alps. In the great cathedrals of France and England the names of the designers is in most cases unknown, but in

Italian architecture individual names are brought prominently before us.

Among the more prominent I may mention Arnolfo, son of the German architect whom I have already referred to as giving the design for the first Gothic building in Italy. Arnolfo's name is associated with the great Duomo and the church of Santa Croce at Florence.

Pisa, a celebrated centre of Mediæval art, sent forth a number of sculptors and architects, but her most distinguished son was Nicola Pisano, whose sculptures adorn the cathedral at Siena and Orvieto, and who furnished the design for San Antonio at Padua and probably for the cathedral at Orvieto. His son Giovanni was scarcely less distinguished than his father.

In the following century Giotto, distinguished as a painter as well as an architect, constructed buildings in the Gothic style, of which the campanile of the Duomo, at Florence, is the most distinguished example. These men, with others I might mention, not only impressed their individuality upon their works, but formed centres or schools of design.

Apart from the local types of the Gothic style and the personal influence to which I have alluded, we have occasional buildings in which local influence is not evident and where the design is so unlike other Italian buildings as to suggest foreign influence: the most notable example of this influence is found in the greatest of all Italian buildings, the cathedral of Milan.

I might go on to mention in detail features of Italian buildings that attract the attention of the traveller who has previously visited the great cathedrals of the north, and who at once realises that he is in a different art atmosphere. He will notice the absence of buttresses on the flanks of the buildings, the absence of flying buttresses, the small size of the windows and the absence or meagreness of tracery with which they are ornamented, the absence of coloured glass, the absence of triforiums over the nave arches and the meanness of the clerestories. He will notice how columns are used singly or in pairs, and the use of colour on the walls. Of these details time forbids me to speak, but before closing I will mention one material used in the construction of Italian buildings that meets us at every stage in our study of Gothic architecture, that is, bricks and terra-cotta. Italian brickwork is remarkable for the skill shown in the use of what we are inclined to deem an inferior material in the elaboration of arches, tracery, cornices and mouldings, but as this is a subject somewhat foreign to this paper, and one that requires an evening for itself, I only refer to it.

## TESSERÆ.

### English Railways.

THE great cry in our day is that nothing has any right to exist which does not pay. The cry in some measure reproduces itself. If the beautiful has such attractions for humanity, humanity will exact its presence in every work whose existence depends upon its patronage. But humanity's appreciation of the beautiful is weak, while its appreciation of its pecuniary interests is strong. Hence the man who consults taste in his undertakings is miserably beaten by the man who consults his pocket. An engineer of the greatest capacity determined, at the outset of railways, to construct a line which would combine all the requirements of art with all the purposes of utility. He therefore built cyclopean engines and Acherontian tunnels. Every bridge which spanned a mountain torrent or a bridge road charmed the eye with its variegated coping. He piled colossal arches upon gigantic buttresses, to aggrandise as well as beautify the chasms through which threaded in graceful windings the rails of the broad gauge. The public taste was gratified, but the shareholders were ruined. While lines of cheaper construction, executed by men of far inferior ability, yielded a handsome dividend, the broad gauge would not pay. Since the failure of Brunel all railways have been constructed upon the economic principle of spending as little as possible consistently with the permanence of the traffic. The great struggle is to combine the minimum of expenditure with the maximum of receipts. In pursuance of this sublime object wherever railways establish their suburban quarters the trees are cut down and the country laid desolate. The fields disappear beneath grim erection-sheds and black showers of ashes. Blank walls and dismal bridges oozing with slimy filth start up in every conceivable variety of ugliness. These deformities are usually associated with sooty tunnels, yawning as if for more fields to swallow, and miles of mud embankment and lath-and-plaster desolations which greet us at every turn, until the mind associates railways with the very incarnation of unsightliness, as a sort of vampire whose breath blights the ground whereon it sets its foot. But railways are so useful we can tolerate the eclipse of the beautiful which characterises all their creations, though we suspect if such things had sprung up in ancient days they would, like those aqueducts which brought

the limpid waters of Terni and Clitumnus to the inhabitants of Rome, have harmonised with the beauty of the most delicate of landscapes, and displayed in their structure the weird grace and spiritual loveliness revealed in the dynamical forces of nature.

### The Venus of Melos and Raphael's St. Margaret.

No one can study the Venus Victrix of the Louvre without being almost enthralled with her loveliness. It is impossible to describe the mingled grace and dignity of her figure—the idea it gives of overflowing life and elasticity, the queenly pose of her head, the expression of freedom and of triumph, conveyed not in the face alone, but in her whole attitude. As far as such mingled power and loveliness can satisfy you, there is nothing more to be desired. But the merely earthly beauty of her face, the self-assertion of her attitude, the stony scorn on her lovely lips hardly satisfy one's ideal of pure womanhood, and certainly do not raise our thoughts to anything higher than that. She might very well stand for Venus looking on, whilst at her own command Psyche is being tortured at her feet. In one of the picture galleries above is Raphael's *St. Margaret*. Very young, younger than Venus, little more than a child, St. Margaret has come through the gloomy valley that stretches far behind her, and now at its end, amidst desolate rocks and gloom, she has met the Dragon who came out to drive her back or to destroy her. And she has conquered her foe: she, too, is Victrix. It may be the palm branch in her little outstretched hand, it may be her most innocently lovely face that has overthrown him; however that may be, he lies prostrate before her, gnashing his teeth and helplessly clutching the air with his tremendous claws, whilst he lashes the ground with huge coils of his serpent tail, vainly seeking to enfold her. She has conquered, but she is not conscious of her conquest, though her little feet are treading on his loathsome bat-like wing; she does not even see him. Forgetting all that is past, all her mind is bent on that which lies beyond, as with a modest childlike grace she steps carefully onward, without triumph as without fear. Her pure wide-opened eyes are earnestly fixed upon the upward path that leads her to her Lord. Setting aside Christian and Greek faith for the moment, we maintain it is worth while to consider how essentially different are these two types, not in degree, but in kind; how wide apart is the finite life expressed in the Venus, and the life foreshadowed in St. Margaret's wistful gaze, between the self-contented, self-regarding soul of the one, the purity and self-forgetfulness of the other. And which of these two is the highest, and therefore the truest ideal of womanhood, which ennobles our thoughts and elevates our aspirations the most when we study it?

### Dürer's Architectural Designs.

In the print-room of the British Museum is a very large square folio volume, nearly filled with drawings by Albert Dürer—at all events they are attributed to him. His drawings are done in moderately thick lines, either with black or dark brown ink, and betray most certain traces of compass points, ruling pens and bow pens. One drawing is the plan, looking down from above, of a most complicated fountain or pinnacle. There are pinnacles and pediments of an S-shaped plan, and indeed it resembles the almost impossible architecture that Israel Van Meekin designed on paper and Adam Kraft executed in stone. There are a great many compass holes in this drawing, as if it had been pricked off. It is most carefully done, and the sections of the mouldings have the beads turned in with the bow pen; the lines of operation, such as the centre lines, are merely scratched on the paper, as it does not appear that they had means of erasing the lead lines. Another drawing represents a tomb evidently Italian, beneath a vault supported upon four pillars; the drawing is done in black, and elaborately shaded with the same colour mixed with white; the lines are ruled. There are likewise designs for sundry pieces of jewellery; these are outlined in black or dark brown, and then very slightly coloured with light washes of colour, the raised parts being left white. One design would appear to represent a large vase or fountain of the most elaborate description; from it the various figures pour out streams of liquid, and being coloured red in one case may represent wine. There are two hands a little below the middle, which hold out cups, similar to those attached to the drinking fountains of the present day, to receive the noble juice. Indeed, this design would make a most charming drinking fountain if executed in copper and enamelled, or indeed even in stone, painted. Three or four leaves of the book are occupied with a coloured design for a baluster column covered with arabesques; the drawing is most vigorous, and the colouring leaves nothing to be desired. The other drawings are more remarkable as curiosities than as having relation to architecture. Thus, there is the figure drawn from the model which he afterwards used in his beautiful plate of *Fortune*. The original figure is covered with squares, drawn with sharp points, evidently for reducing or enlarging it. At page 143 is a bird remarkably like the dodo; and further on a full-sized elevation

and plan of a shoe of the period, and a most valuable drawing for the writer on costume. Dürer, in fact, appears to have had all the conveniences and appliances of modern times as regards his architectural drawing, but it is evident that his bow pen was none of the best, as his circles are the least neat parts of the drawings.

### The House of the Fountain, Pompeii.

Adjoining the north wall of the fullonica is a house, not particular from its dimensions, but adorned with a fountain of so remarkable a structure that the habitation was distinguished for some time by no other name. The house of the fountain is approached from the street of the Mercuries by a handsome and lofty door, and the atrium is not less than 50 feet in length by 40 feet broad. This atrium has its ala on each side, regularly disposed, with its tablinum in the centre, and beyond it a portico with a small court, the wall of which is painted to represent a garden. In the tablinum is a painting of goats. The whole ground-floor of the house consists of eleven rooms, without reckoning the alæ, the atrium or the portico; and it seems to have been the property of a person of consideration. The inner portico has only three columns, and those of a degraded Corinthian; nor are they at equal distances from what may be termed their antæ. The fountain also, though nearly in the middle of the garden, which is not rectangular, is neither placed opposite an intercolumniation nor opposite the centre of the tablinum, so that it must have lost much of its effect. The colours and the plaster have long since fallen. There was a private entrance through the faux, and a back passage from the vicus of the tragic poet. Near the faux was also the staircase for ascending to the upper floor. The fountain itself was, however, the great source of the modern celebrity of this habitation, presenting, in fact, several circumstances calculated to strike an observer. First, its form is precisely that which every citizen would erect as a fountain at the bottom of his garden, and such as may be seen at the present day in the courts of most of the palaces in Rome and throughout Italy, and proving that the worse the taste the better chance it has of being handed down for imitation from generation to generation. Secondly, the materials are of a singular description, the whole being covered or encrusted with a sort of mosaic consisting of vitrified tesserae of different colours, but in which blue predominates. These are sometimes arranged in not inelegant patterns; and the grand divisions, as well as the borders, are entirely formed by, and ornamented with, real sea-shells, neither calcined by the heat of the eruption nor changed by the lapse of so many centuries. It has been said that a boiler or cauldron in this house was so contrived that hot water could, if necessary, be conveyed to the cistern, or piscina, which advances in front of the fountain. We are exceedingly apt to accuse the ancients of ignorance in natural philosophy—an imputation which the excavations of Pompeii have contradicted. Pliny states that water in leaden pipes will rise to the height of the source whence it is derived; and in the *Sylvæ* of Statius it is clearly shown that the Aqua Marcia passed the Anio in leaden pipes. But Vitruvius gives instructions for the conveyance of water in tubes, and Pliny mentions the custom as common in his time. The two fountains of Pompeii confirm the written testimony. Neither does it seem that the use of shells in the decorations of a fountain is first noticed in the excavations of Pompeii; for Cicero, in his Formian villa, appears to have employed them.

### Greek Painting.

Greek painting perhaps would share all the praises bestowed on their sculpture, had time and the barbarity of mankind allowed us to be decisive on that point. All Greek painters are allowed is contour and expression. Perspective, composition and colouring are denied them; a judgment founded on some bas-reliefs, and the ancient (for we dare not say Greek) pictures at and near Rome, in the subterranean vaults of the palaces of Mæcenas, Titus, Trajan and the Antonini, of which but about thirty are preserved entire, some being only in mosaic. Turnbull, to his treatise on ancient painting has subjoined a collection of the most known ancient pictures, drawn by Camillo Paderni and engraved by Mynde; and these alone give some value to the magnificent and abused paper of his work. That Poussin much studied the pretended Aldrovandine nuptials; that drawings are found done by Annibal Carracci from the presumed Marcus Coriolanus; and that there is a most striking resemblance between the heads of Guido and those on the mosaic representing Jupiter carrying off Europa, are remarks long since made. Indeed, if ancient painting were to be judged by these and such like remains of fresco pictures, contour and expression might be wrested from it in the same manner. For the pictures, with figures as big as life, pulled off with the walls of the Herculanean theatre, afford but a very poor idea of the contour and expression of the ancient painters. Theseus, the conqueror of the Minotaur, worshipped by the Athenian youths; Flora with Hercules and a Faunus; the pretended judgment of the Decemvir Appius Claudius are, on the testi-

mony of an artist who saw them, of a contour as mean as faulty; and the heads want not only expression, but those in the Claudius even character. But even this is an evident instance of the meanness of the artists, for the science of beautiful proportions, of contour and expression could not be the exclusive privilege of Greek sculptors alone. In perspective there is no comparison between the moderns and the ancients, whom no learned defence can entitle to any superiority in that science. The laws of composition and ordonnance seem to have been but imperfectly known by the ancients; the reliefs of the times when the Greek arts were flourishing at Rome are instances of this. The accounts of the ancient writers and the remains of painting are likewise, in point of colouring, decisive in favour of the moderns. There are several other objects of painting, which, in modern times, have attained greater perfection: such are landscapes and cattle pieces. The ancients seem not to have been acquainted with the handsomer varieties of different animals in different climes, if we may conclude from the horse of M. Aurelius, the two horses in Monte Cavallo, the pretended Lysippean horses above the portal of St. Mark's Church at Venice, the Farnesian bull, and other animals of that group.

### R.I.B.A. Elections.

SIR,—There is an old saying that "Fools make feasts for wise men to eat." No doubt many of the members can afford 1*l.* 10*s.* as the price of a ticket for an Institute dinner, but on a recent occasion only 38 of the 1,600 members of the Institute attended.

But 1*l.* 10*s.* per head did not meet the necessities of the case, and the existing Council added about 30*l.* (from the funds of the Institute) that the select 38 might eat, drink and be merry with the wise men who patronise architecture.

It is to be hoped that a new Council may be elected who will consider that good fellowship and kindly association at the festive board should not be limited to those members with long purses. Under no circumstances should those who cannot afford to be present be compelled, as they have been, to contribute to the cost of the hospitality extended to non-members of the Institute; such hospitality should be at the cost of those members who grace the banquet with their presence and enjoy the company and compliments of their guests.—I am, Sir,

A PLUMPER FOR NEW CANDIDATES.

May 5, 1897.

### GENERAL.

**Mr. Percy Fitzgerald** will on the 13th inst. deliver a lecture before the Society for the Encouragement of Fine Arts on "Robert Adam." This will be his twentieth lecture on the subject.

**Mr. A. M. Butler**, of Finsbury Circus, has been successful in the competition for the higher grade schools at Wood Green. The Tottenham School Board has agreed to accept the assessor's award, subject to some necessary conditions.

**A Committee** has been formed to collect money for the purpose of shingling the spire of Stoke Pogis Church, cleaning the interior, ventilating the church properly, &c., but there is no idea whatever of doing anything that would involve any structural alteration. A large sum of money will, however, have to be expended on the works required.

**The Royal Commission** on the water supply of London has been constituted as follows:—The Right Hon. Lord Llandaff, chairman; the Right Hon. J. W. Mellor, M.P.; Sir John Dorington, M.P.; Sir G. B. Bruce, C.E.; Major-General A. de Courcy Scott, R.E.; Mr. A. de Bock Porter, C.B.; Mr. H. W. Cripps, Q.C.; Mr. Robert Lewis.

**The Restoration** of the north-west arch of Peterborough Cathedral, mentioned in the architect's report of August last as work which might be postponed, is to be proceeded with at once. The committee have also been authorised to carry out such work as may be found necessary to the pinnacles of the north flanking tower and the roof of the north-west gable of the west front.

**The Sale** of the last portion of the Goncourt collections took place in Paris on Saturday last, when the modern engravings realised 26,962 francs. The total amount received for the collections is therefore 1,367,992 francs, which will be available for founding the Goncourt Academy.

**Lord Lovat** has presented to the Council of Kilmorack (Beaulieu, N.B.) a site for the proposed public hall and parish offices.

# The Architect.

## THE WEEK.

THREE notable architects have passed away. The ablest was GEORGE GILBERT SCOTT, who died on the 6th inst. Notwithstanding that he was hampered by some of the waywardness which too often accompanies genius, he produced admirable works. He was a thinker, and probably no man of our time gave so much attention to the principle of evolution as exemplified in Christian churches. One of the fruits of his studies was the large and learned volume on Ecclesiastical Architecture, in which many points are considered which were neglected in ordinary histories. His principal architectural work is the church in Norwich erected at the cost of the Duke of NORFOLK. Mr. SCOTT was Sir GILBERT'S eldest son. He was educated at Cambridge, and won a Fellowship in Jesus College. He was one of the numerous architects who were trained in the Spring Gardens office, but he could hardly be considered as a representative of its Gothic. Mr. G. T. ROBINSON ("Metz Robinson") of late years devoted his abilities to industrial art as director of a large establishment. We published recently some illustrations of rooms in ocean steamers by him, and he took extraordinary interest in such work. He was engaged in preparing for *The Architect* some articles on the treatment that was desirable, which he was not destined to complete. Mr. ROBINSON was more than a designer, for he had a thorough knowledge of several kinds of craftsmanship. JOHN J. COLE was one of the few survivors of those architects who joined the Institute in its first decade. He was then living in Lambeth. His principal work is the Stock Exchange, which, owing to the difficulty of admission, is not much known to the public, but it is a worthy Temple of Mammon.

THE tribunal of appeal in connection with the last Building Act would be an absurdity if litigants could approach it without following a regular procedure, or, in other words, passing to it from an inferior tribunal. The judgment given this week in *Reg. v. London County Council* not only reveals that fact but also another no less important, viz. that the Council cannot be compelled to deal with cases which are supposed to be illegal. A Mrs. WEBSTER built a wall at a less distance than 20 feet from the centre of a road in Deptford, and then erected stables near the wall. The builder was summoned and convicted, but he did not remove the wall. Proceedings were then taken against the lady. She applied for the consent of the Council under section 13 of the Act of 1894. In cases where a departure from the 20 feet regulation is considered expedient the Council is allowed some discretion, and then an appeal might be made to the tribunal of appeal. The Council did not hear the defendant's case, and consequently a mandamus was applied for, and a *rule nisi* granted. The Council applied on a motion to have the order discharged. Mr. Justice HAWKINS came to the conclusion that the consent to a departure must be given before the building was erected, and that there was no clause to compel the Council to consider questions relating to structures which did not comply with the Act. A similar view was taken by Mr. Justice WRIGHT, and consequently it was declared that there was no right to grant a mandamus. The case is therefore important as suggesting what are the duties of the Council in extraordinary cases, and it is possible that the wall and stables may have to be removed.

ANOTHER case arising out of clause 13 was heard at the Lambeth Police Court on Tuesday. A large lodging-house for men is in course of erection by Lord ROWTON and his friends in Churchyard Row, Newington. As it was considered that the building came nearer to the centre-line of the roadway than was prescribed, a summons was taken out against the managing director by the district surveyor, Professor BANISTER FLETCHER, for failing to comply with a notice of irregularity. The Council required that the building should be set back so that every part of the external walls should be at the proper distance from the centre line. The company had the option of applying

to the Council for their consent to the erection of the building; but that course was declined, on the ground that there was no contravention of the Act. Judgment was reserved by the magistrate. This seems to be a case in which there would be no difficulty in invoking the tribunal of appeal after the consent of the Council had been given, for Section 19 says:—"Whenever any applicant under Part II. of this Act, for the sanction of the Council to the formation or laying out of a street, or the adaptation of a street or way for carriage or foot traffic, or for the certificate of a district surveyor, is dissatisfied with the refusal or conditional grant of such sanction, or with any condition imposed by the Council, or with the refusal of such certificate as aforesaid, he may appeal to the tribunal of appeal."

THE limitation of power in the English Courts in dealing with the acts of trustees of property was exemplified by an appeal heard before Lords Justices LINDLEY, LOPES and RIGBY on Wednesday. An application was made to Mr. Justice KEKEWICH by trustees under a deed asking the Court to authorise them to raise by mortgage a sum of 8,500*l.* for the purpose of pulling-down and rebuilding some houses in Grosvenor Street and New Bond Street, which form part of the property which is the subject of the settlement. The houses in question are old and very inferior, and if they were taken down and rebuilt as proposed the value of the property would be increased from 19,000*l.* to 32,000*l.*—an increase of 4,500*l.* beyond the 8,500*l.* to be expended. The settlement, however, does not contain any provision authorising the trustees to raise the money, and the Settled Land Acts do not apply. Mr. Justice KEKEWICH considered he had no jurisdiction to do what was asked, and declined to make an order. Mr. MONTAGU, the owner, who entered into the settlement for the benefit of himself and his family, appealed. The Court dismissed the appeal. Lord Justice LINDLEY said that no member of the Court could see his way to hold that there was jurisdiction, although the acknowledgment was a blot upon the jurisdiction of the Court. Lord Justice LOPES said there was no doubt it would be for the benefit of the persons interested in the property to authorise the trustees to do what was proposed, but that was not enough to give the Court jurisdiction. Lord Justice RIGBY concurred. It certainly does seem remarkable that a man who endeavoured to secure himself and his family by adopting every precaution which the law could furnish, by that act deprives himself of power, and moreover the Courts are helpless to aid him. The invincibility of a settlement is, however, once more declared.

UNDER the Plumbers' Registration Bill, by which powers are sought to establish a national council for the registration of plumbers, it is proposed to have a general council to carry out the provisions, besides two branch councils, one for Scotland and the other for Ireland. It is not intended to have any representatives of Government departments. The term of office for the Council is to be five years, but members can be re-elected. It is proposed that the first council should quit office on January 1, 1901. The president of the council is not to hold office for more than five years, and the first business of the council will be the co-option of twenty additional members.

IN the course of the experiments on materials which the United States Government have instituted, stone was not overlooked. According to the *American Architect*, it has been found that temperature and moisture have a very great influence in determining the resistance of stone. In order to measure the permanent expansion which is known to take place in stones after soaking in water, a large number of samples were soaked in water at 32 deg. Fahr., then in water at the boiling-point, and again in the cold water, and afterwards dried. On measurement, all the stones so treated were found to be larger than before, the actual linear expansion being from one-fifth to one-tenth of 1 per cent. On testing for resistance to various strains, however, the strength was found to be greatly affected by the water treatment.

## ARCHITECTURE AT THE ROYAL ACADEMY.—III.

THERE are some drawings of churches hung within a limited space which are suggestive of the variety of aims which are now in the minds of architects. Mr. J. O. SCOTT's new Church at Harrogate follows a severe type of Gothic, but still more severe is the new Church at Bentley, near Doncaster, by Mr. JOHN CODD. St. Thomas's Church, Exeter, by Messrs. HALL, COOPER & DAVIS, is more suggestive of a desire to make an exterior attractive, while in Mr. MOUNTFORD's new East End, St. Anne's Church, Wandsworth, we have undoubted Italian with an altar-piece. The last is one of the indications of a change in architectural fashions, and we see another, and one no less remarkable, in the Additions to Savoy Hotel, by Mr. COLLCUTT, in which we find a court with fountain and arcading which seem to be transplanted from an Italian town. Italian also is the design for a Stone Bridge by Mr. G. B. CARVILL, but we are afraid it is never to be realised, for the days of bridges in cut stone have passed away. Even the Parisians have substituted steel in the new bridge which is to serve as the memorial of the Russian alliance. Another student's work is Mr. A. G. QUIBELL's Municipal Buildings, which may be called English Classic in style. Mr. MURRAY ROBERTSON, of Dundee, follows the example of many of his countrymen who are architects in avoiding a Scottish treatment for the Lochee Free Library and Baths. Unless English architects come to its rescue, the northern style, with its tourelles and corbie-steps, will soon be extinct. The Girls' School, Hammersmith, proposed by Mr. R. BLOMFIELD, differs from the ordinary Board school, and forms a sort of educational temple which would be satisfactory in appearance. The same architect has a design for Parish Institute, Portsea, which looks as if it were intended to keep out invaders. We also see Penn Mill Board Schools, by Mr. J. N. JOHNSTON; House at Walton-on-Thames, by Mr. J. WATSON; and Stable at Harrow Weald, by Messrs. FORSYTH & MAULE, each being an ordinary example of its class. Mr. F. W. BEDFORD has a solid, cubical, old-fashioned and apparently comfortable red-brick mansion, Shirebrook Dene, Headingley. Mr. HUNTLY-GORDON has another example of his music-rooms, in which he usually insists on a high open-timber roof. The room shown is for erection in a house in Harley Street, where it must provoke contrasts.

The title of Mr. DYMOKE-WILKINSON's design, "A suggested drawing-room fireplace in coloured gesso-duro, stained alabaster and gilded bronze," may excite expectation of a gorgeous arrangement; in reality, the fireplace is a quiet black-and-white arrangement of the story of St. GEORGE and the Dragon. The design for rector's stall, Wallasey Church, by Mr. COGSWELL, shows a canopy supported by tall columns, but so slight, the occupant can hardly be said to be aloof from his congregation. In Mr. W. H. SETH-SMITH's new house at Eastcote, Pinner, red and white are commingled. The roof is in red tiles, the lower part is red brick, and between them is the upper part in white, diversified by half-timber work. The garden is of the formal type. The design for a font in cast and decorated lead, by Mr. G. C. CARTER, is worth notice. Any advantages which the material may possess are not easily made apparent in a drawing. The font looks heavy, and does not manifest any superiority to one carved in stone. The design for Queen's Palace, Empire of India Exhibition, 1895, by Mr. A. B. ROBB, recalls one of those Indian buildings on which Italian architects are supposed to have co-operated. The arcades are adapted without much difficulty for a row of shops in the lower part.

The New Boarding Houses for Westminster School, by Mr. T. G. JACKSON, recall some of the old houses which still survive in the neighbourhood of the Abbey. They are built of buff and red bricks, swags and shields are introduced between the windows, and the roofs are tiled. Mr. JOHN CASH has a long two-storey country house with capacious windows. Messrs. WIMPERIS & ARBER's Bungalows, Herne Bay, are also two-storey buildings of red brick and half timber, with a projecting porch. The Old Houses, York, drawn by Mr. F. L. GRIGGS, are curious as suggesting how small was the value set on light when they were erected, for unless the door was kept open the lower part must have been in semi-darkness. The billiard-room

appears to be gaining importance. In the example given by Messrs. HESKETH & STOKES the dais has a room to contain it. The principal room is panelled, with a curved ceiling, and suggests that it was built for its purpose. The Hall at Ford Manor, Lingfield, Surrey, by Mr. J. L. WILLIAMS, has groined ceilings supported by massive columns, and the recesses at windows are so large they could easily be converted into rooms. Mr. THOMAS GARNER has a fine design for the monument of Bishop DURNFORD in Chichester Cathedral. It is a canopy tomb very elaborate in detail, with a reclining figure of the bishop. The structure will be a desirable addition to the cathedral, where the deficiency of memorials is one of the causes of the lack of interest which tourists experience on visiting the building. The house, Vlierboom, Zürich, by Mr. A. KOCH, is a sort of combination of Elizabethan and Flemish, which can hardly fail to be impressive if realised as drawn. Less elaborate are the three houses by Mr. T. ALLEN, Mr. T. BALLANTINE and Messrs. SWANSTON & LEGGE.

For the proposed Church of St. Columb, Lancaster Road, Mr. W. A. PITE has adopted Romanesque. The piers are of red and white bricks, and in the apse the altar is covered by a ciborium larger than any of those used in English churches; the roof is a flat vault with parallel transverse ribs. The design is worth study, for Romanesque has many advantages to recommend it for a more general adoption in England. Vectis Lodge and Woodbourne, Edgbaston, by Messrs. BATEMAN & BATEMAN; the House at Buxton, by Mr. C. H. HEATHCOTE; Nethercliffe, Walton-on-Thames, by Messrs. NIVEN & WIGGLESWORTH, are examples of modern houses in red brick. Mr. J. F. DOYLE has a rather pleasing Wesleyan Chapel. Mr. C. A. NICHOLSON shows some originality in his Font for Cockington Church, Devon, owing to the arrangements for raising the cover, by which the whole assumes almost the appearance of a small baptistery. In the study for Municipal Buildings Mr. H. R. APPELBEE endeavours to cope with the difficulties presented by an awkward site. In the Market Hall, by Mr. H. R. GARDNER, there is a contrast between large and small windows, and by the introduction of armorial shields local interests can be expressed. King James's Grammar School, Knaresborough, by Messrs. HALL, COOPER & DAVIS, is a quaint group of buildings in which the various divisions are sufficiently marked without any incongruity. Messrs. HUMPHRY & HOPKINS's design for Municipal Buildings, Belfast, is as a drawing rather weak. The treatment shows none of the variety which is common among modern buildings of the class in England, but in compensation there is a large dome.

Mr. R. W. K. GODDARD's new church, Clacton-on-Sea, is remarkable mainly for the very large window which seems to emphasise the want of height in the building. St. Aidan's Church, Leeds, by Mr. H. C. HICK, may be said to be of late Romanesque style in the nave or bays, with semicircular arches, and there is an open-timber roof. There is also a rood with figures, a feature that is not derivable from the South, while the baldachino of the altar has spiral columns like those in St. Peter's. In the New Bonded Stores, Vauxhall, there is nothing remarkable, unless the boldly rounded junction between front and side. It is by Mr. A. J. VIGERS, whose house at Rowgardens Wood could easily be mistaken for a small terrace. The directors' private room, by Mr. CASH, shows a comfortable panelled interior in quiet colours. Several architects have co-operated in the Royal Palace Hotel, Kensington. The new ball-room is by Messrs. H. S. LEGG & SON; it is very showy, with ornament in all directions. The recesses on both sides form an arrangement which will be appreciated. Mr. BRIGGS's House at Crowborough is arranged to enable the inmates to enjoy the surrounding scenery; the area of the windows much exceeds that of the walls. The design for the Hotel, Cork, by Sir T. N. DEANE & SON, presents a building standing on the river side. It is simply Flemish in style, and the windows are high and narrow. It is a great improvement on the buildings in the vicinity. Wentley Wood, Yorkshire, by Mr. H. C. FRASI, is another building in which the garden is made to add to the general effect by its quaintness. There is a good deal of half-timber work in the front, which is agreeably broken up. The Prince's Restaurant, Piccadilly, is so generally appreciated since the opening, there can be no doubt the architects,

MESSRS. WIMPERIS & ARBER, have divined what was desired by the public, and their intentions have been efficiently carried out. There is no question of its effectiveness. In this case, also, we find figures forming part of the ceiling decoration, an experiment which not many years ago would have resulted in failure. MESSRS. GOTCH & SANDERS have employed several illustrations to explain St. Mary's Church, Kettering. The details are freely treated, and the large buttresses on the exterior add much interest to a building which is of a simple character. The view of St. David's, Exeter, by Mr. W. D. CARÖE, is taken from a point of view so close to the west front that the ecclesiastical character of the building is not so apparent as is desirable. MESSRS. GARDINER & HAYES have a design for the Clench-warton Board School, in which the parts are well balanced. A premiated design for the Agricultural School, Newport, by Mr. G. S. NICHOLAS, shows a rather severe building arranged round three sides of a court; but in this case a plan should have been given. Mr. FORBES GLENNIE has a west country church. Mr. T. W. CUTLER contributes a view of his Convalescent Home, Epping Forest. A fine drawing displays Mr. PEARSON'S design for the rood-screen in Bristol Cathedral. There is a solid base, and for the uprights, or piers, groups of figures are so arranged as to serve instead of ordinary capitals. Alvaston Hall, Cheshire, is a large building remodelled by MESSRS. SALOMONS & STEINTHAL. The sketch of a Dutch Renaissance Dining-room, by MESSRS. S. J. WARING & SONS, suggests the architectural skill possessed by the firm, which enables them to carry out architects' own designs with fidelity. Sculpture is used to increase the effect, and there is an absence of commonplace features which is satisfactory to see. Mr. TREVAIL'S Free Library and Technical Schools, Cornwall, is disappointing, but some of the defects of the building may be due to the drawing, which is not up to the average Academy standard. The design for a new Church at Exeter, by MESSRS. DEMAINE & BRIERLEY, is noteworthy for the tower, which looks as if the designers wished to suggest that it was a pharos. The view from the tower at Kincardine, by MESSRS. NIVEN & WIGGLESWORTH, is boldly drawn; the building possesses some northern characteristics. The Lecture Hall of the Technical Schools for the Corporation of Liverpool, by Mr. E. W. MOUNTFORD, has the roof arranged as a flat curve, in order to aid acoustic effects. There is a dais at one end, which will be of service on occasions when prizes are distributed. It might be expected, however, that so wealthy a corporation would authorise a larger expenditure of money to enable decoration to be introduced in so important a room.

We have not noticed the designs for stained-glass and other classes of work which are not produced by architects.

## PAINTING AT THE ROYAL ACADEMY.—II.

THERE is not much which can be considered novel in Gallery VII. It shows some courage in Mr. LOGSDAIL to introduce STERNE in a picture, and to suggest he was not the hypocritical sentimentalist which is now the current verdict. He is omitted, however, from the title, which is *Maria*, from the "Sentimental Journey," but it is evident that on STERNE most labour was bestowed by the artist. The luckless *Maria* has too much resemblance to a model to be altogether satisfactory. There is a contest for the position of fashionable portraitist, which is vacant since Sir J. E. MILLAIS'S death. If a suggestion of mind and character was of any importance compared with physical form, Mr. WELLS would have a chance, but he is likely to be outflattered. Mr. SARGENT has so many backers he may win the prize. Of all his portraits this year his *Hon. Laura Lister* is the best able to sustain criticism. The little maiden, in her old-fashioned black silk costume, has all the genuine *naïveté* of one who is not at complete ease before the artist, and the slight commotion has been caught with the rapid insight of a master. We see none of the pertness of the modern society child, and as a record of simplicity which will soon vanish in the world, the portrait is comparable with one of Sir J. E. MILLAIS'S representations of childhood. But the hideous

vase and pedestal could hardly be matched among the properties of a Whitechapel photographer. Mr. SARGENT apparently has yet much to learn. We have grumbled over the fascination which autumn exercises over Mr. J. W. NORTH, and from which he is unable to emancipate himself. He is a companion for Mr. FARQUHARSON, the snow painter, and if we could only discover two other painters for spring and summer the circle would be complete. But the most hypercritical cannot help enjoying so delightful a transcript from nature as *An English Western Valley*. The signs of change are hardly apparent; we see autumn in its ripeness, with so many subtle variations of green among the trees that the red apples which are introduced appear to be unnecessary, and only a painter's means to heighten effect. But Mr. NORTH cares little for such tricks; he does not even show a figure of man or beast to suggest scale; we have simply greenwood trees which have matured according to their own laws, and exist without any relation to other organisms.

In Gallery VIII. Miss HENRIETTA RAE, we are glad to say, proves that an effete mythology has not irresistible power over her pencil. We must get rid of the science which shapes our ways before we can paint or enjoy Greek legends. Like KEATS the poet, Miss RAE feels the necessity of representing beings in whose veins ichor has to give way to blood. ISABELLA of the pot of basil seems doomed to serve as a sign of a transitional period. For the pre-Raphaelites she stood between modern and scriptural scenes; in the present case she is not unlikely to come midway between mythology and modernity. The artist was always excellent in representing form; in *Isabella* she has proved herself to be an admirable colourist, whilst the infatuation of the lovelorn girl could hardly be expressed more ably. The only drawback is the mock antique table, which is too familiar in the cheap furniture shops to be worthy of reappearing in such a painting.

Gallery IX., as usual, is assigned to cabinet paintings, and is one of the most interesting, for there are over 200 examples and the percentage of unattractive works is smaller than in the other galleries. Mr. A. WATERHOUSE'S *Bamborough Castle* has little that is amateurish in any part, and the subject requires skill in painting water, sky and land, as well as buildings. *Battersea*, by Mr. E. BLOUNT SMITH, is a more pleasing subject than the name would suggest. Mr. ALMA-TADEMA'S *Her Eyes are with her Thoughts, and they are Far Away*, is characteristic, although there are signs of change in his work this year. He would be generous enough to acknowledge that Mr. C. F. LOWCOCK'S *Doubtful*, while suggesting his influence, approaches his standard of execution. A colourist is revealed in Mr. DUDLEY HARDY'S *The Favourite*, which at the first glance might be supposed to be an enamel.

Mr. KENNINGTON'S *Maternity*, in Room X., might be taken as evidence that he had not found the right path when he occupied years with pictures of the most indigent classes, and who as models could not present graceful forms or healthy tones. The subject is popular, and all the parts are painted with a breadth which is not found in the artist's earlier works. The most remarkable picture in Gallery XI. is the *Childhood* of Mr. CHARLES SIMS. It is such a scene as may often be witnessed during a summer's day on Ashted Downs and similar places round London. A big school is revelling in the novel liberty of occupation of ground where no gardener has sown seed and trespassers are not in danger. Mr. SIMS has endeavoured to suggest the haze which sometimes overspreads such places and does not avoid the visitors. A more difficult feat has not been attempted this year. There is perhaps a little excess in the effects, as if the ground and the children were seen through gauze, but it still remains one of those pictures which are full of promise for English art.

We hope it will not be concluded that we believe there are no more pictures in the Academy than those we have pointed out. That would be erroneous. We have simply mentioned those which appeared to be most remarkable for their novelty. Many others are to be found which will give pleasure to visitors. Among them are Mr. PETER GRAHAM'S *Where Naught is Heard but Lashing Wave and Sea Birds' Cry*, a picture so excellent as to atone for the length of the title; Mr. DRAPER'S *Calypso's Isle*, Mr. GOW'S *Waiting for Prince Charlie*, Mr. BRETT'S *Castel Moel and South Stack*

*Lighthouse*, Mr. ALMA-TADEMA'S *Watching*, Mr. H. W. B. DAVIS'S *Flowery May*, Mr. MACWHIRTER'S *Childe Roland* and *Alpine Meadows*, Mr. LESLIE'S *Day of Rest*, Mr. J. C. HOOK'S *From the Shore to the Field*, and portrait, *Alan J. Hook, Esq.*; Mr. A. GOODWIN'S *The King's Garden*, Mr. LOGSDAIL'S *A Winter Morning on the Mole, Venice*; Mr. CORBET'S *Vespers*, Mr. BLAIR LEIGHTON'S *In Time of Peril*, Mr. LEADER'S *Autumn Gleam*, Mr. MARGETSON'S *The Sea hath its Pearls*, Mr. JACOB HOOD'S *Little Swineherd*, Mr. G. HITCHCOCK'S *St. George* and Mr. T. GRAHAM'S *Young Crusoe* forming as liberal an allowance of enjoyable pictures as can be expected in prosaic times.

### "THE INSTITUTE ABROAD."

THE play-room is as indispensable as the school-room. To those who think of the future of English architecture, the members of the Architectural Association as actors or as auditors of "The Institute Abroad" at the St. George's Hall on the 6th inst. were as hopeful a sight as when attending classes or taking part in the conference on examinations. The whole session is, however, occupied with very hard work, and this year as on former occasions the dramatic and operatic performance was compelled to be almost improvised; libretto, music, study of parts and rehearsals had to be got through in less than a fortnight. It would be impossible to do so much if the Association were not provided with an inexhaustible subject for ridicule—to wit, the Royal Institute of British Architects, the possessor of two Royal Charters. The purpose of that body is not evident to its highest and oldest officials, for beyond serving as a registration office it is of doubtful utility, but it would be hard to match it as a subject for laughter. What adds to the piquancy of the occasions when it inspires an architectural Aristophanes is that those who mock and those who enjoy the mockery may one day act as councillors and committeemen, or, in other words, become responsible for carrying on the illusion. When that time arrives they are pretty sure to confess to one another that their fictions did not reach the reality, for the Institute is, to those who have had experience of its inner workings, a more absurd creation than imagination can present. Some courses of burlesque would, therefore, appear to be indispensable for all who aspire to sustain the responsibilities of office at the Institute with decorum and dignity.

This year the operations of the dramatists' Institute were supposed to be conducted in old Algeria. Under its auspices we find that women are not only freed from Moorish thralldom, but they take part in its architectural competitions. They produce such lovely designs as give the Council shocks, for those respectable judges can never discover what the drawings signify. But as there are not prizes enough at disposal, the Council have devised a new series to reward the fair votaries of the mother of the arts. The first prizewoman is to marry the president, to the second the secretary will fall, then the librarian, and so on to the end of the official list in the Kalendar. How long the marriage is to continue binding appears to be undefined, for there is no copyrighted form relating to espousals included among the Institute publications. The notice relating to dangerous structures probably suffices for the Algerines. The sweet girl graduates merit all the joys which can come to them, for they are genuine students. Rivington is to them a darling, Fergusson a duck, and Freeman a dear. But, as is natural, their affection for the authors of bound volumes is not satisfactory to those who get up Institute brochures, which have high prices imprinted on the covers. The jealous librarian accordingly offers to lend them back numbers of the Transactions, a strange periodical which is not supposed to be read by those to whom it is addressed, and never leaves the wrapper until it has found its way to the waste-paper shop. With the aid of Institute literature the fair students are expected to uphold the dignity of the profession.

While the conversation is in progress there enter three joyous A. A. Travelling Students, John Jones, Patrick W. Brown and Charlie Robinson, on a sketching tour. Of course they discover that even in Algeria there is cribbing from England, for at their first glance they perceive a finial which is manifestly related by its curves to the new entrance of the Alhambra in the Charing Cross Road. But characteristically

the Secretary of the Institute objects to the give-and-take principle, for a copyright has been secured by the Council in all the details of the mosques, however old. Soon the Emperor enters, who is a living statue and an adept in all the arts. The imperial duties were so multifarious, his Majesty was unable to be present at the Jubilee banquet on the night preceding, and he was unable then to continue a conversation, sing a song, or perform a jig. Mr. Charlie Robinson is, however, no less anxious to discover the whereabouts of that well-known public man, Mr. Blarney Barnooley, than to seek examples of English design among the Algerines. There is no record of such a name on the librarian's list of authors, and that official generously offers to insert an advertisement free of charge in some Institute publication. But Mr. Robinson considers it will be useless, an opinion in which some other people whose advertisements are not gratuitous would, no doubt, agree.

When officials and travelling students depart, Mr. Barnooley enters, accompanied by a delightful young lady, a student of the arts called Tricksey. They are first struck, not with Moorish details borrowed from London, but by an announcement that a President is wanted for the Institute, and offering the munificent salary of 15*l.* a year, all found (or 16*l.* if the successful man is an early riser), and one night out in a fortnight. A gentleman with some knowledge of architecture would be preferred; no beer is given, and no washing, but instead one annual excursion. No Frenchman or foreigners are eligible. With his usual decision Mr. Barnooley resolves to go in for the appointment. He addresses himself to the librarian, who offers to put his name down on the register for a shilling, but on learning the applicant's aspiration takes him in in order that he may fill up a form expeditiously. While the process of filling up the necessary form is in progress Mr. Robinson re-enters, and discovers that Tricksey is an old flame of his, who is more attractive than any finial. His demonstrations of affection are not, however, approved of by the ubiquitous and severely moral librarian. The President in posse somehow contrives to make behind the scenes the acquaintance of the Emperor, and they join in an interesting financial discussion, and exemplify their theories by playing with cards of a rare variety which no stamp duty can legalise. The Sultan loses, and is compelled to leave the ancestral signet ring in pawn with its jewel, beside which the Koh-i-noor is like unto a mustard seed.

Then comes that momentous event, the election for the President's office, and it is needless to say Mr. Barnooley is successful. The marriages are to follow. In the interval Mr. Robinson makes a pathetic appeal to Tricksey, in the hope of saving this modern Andromeda from the monster of a President. "Shall it be all in vain," he asks, "that I have won Soane medallions, Grissells, Pugin studentships by scores, storming the very battlements of fame in passing the Institute Exam., that I might lay them at your feet; and besides, have I not spent sleepless nights burning the candle of ceaseless diligence that I might qualify as a district surveyor, and earn a miserable pittance to support you?" He implores her to fly with him to some distant shore where they could spend their days in the pursuit of art, untrammelled by horrid necessities of practical construction. But the thought of becoming Mrs. President and receiving the guests at the conversazione is too much for the vain girl. Probably she imagines she may be concerned in settling arbitrations.

The first act of the new President is to endeavour to get rid of his ring. He offers it by auction, and is ready to accept 2,000 guineas for it; but as the biddings do not exceed five shillings, he thereupon promotes the Grand Diamond Jubilee Architectural Co-operative Syndicate, Limited, with a capital of 5,000,000*l.* The Sultan-Emperor is not satisfied with the arrangement, especially as he discovers that his wonderful diamond is one of the assets of the company. Accordingly his Majesty confiscates the ring and reserves to himself the nomination of President, with all the privileges belonging to the position. Mr. Barnooley is banished, although his financial dexterity would be useful in manipulating balance sheets. Mr. Robinson is rewarded with Tricksey, and a new era for the Institute commences, for the Sultan resolves that the members of the Architectural Association, being true artists to the backbone, are to rule the Institute for ever and a day, a consummation that would be desirable in other countries besides Algeria.

The success of "The Institute Abroad" was due to the co-operation of several members. Messrs. A. Stalman and G. B. Carvill produced the book, and Mr. Leonard Butler composed the music. Mr. A. Stalman appeared as the Sultan-Emperor, Mr. Carvill as Blarney Barnooley. Mr. Frank Collins officiated as secretary of the Institute, and Mr. Clapham as librarian. The travelling students were Messrs. H. Seton Morris, W. W. Furlong and S. Constanduros. Then there were members of the Council, Sultan's bodyguard, Moorish boys and others. Among the ladies were distinguished Misses Blanche Selig, Grace Wylde and Ada Yerbury. As all worked so well, it would be invidious to criticise particular performers; but it must be said their efforts to amuse did not receive the appreciation from the audience that was merited.

## ELECTRIC SUPPLY AND THE DESTRUCTION OF TOWN REFUSE.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

**REFUSE-DESTRUCTORS** may be found in most towns of fair size, and their adoption is now being contemplated in many smaller ones. Destruction of refuse by fire completely destroys the noxious gases injurious to health. The refuse must, however, be subjected to a sufficiently high temperature and burnt in properly constructed furnaces. These destructors may be erected in populous districts without causing annoyance if the furnaces are properly designed and managed, and they can also be made a success from a financial point of view, when compared with other methods of disposal.

It may be of interest here to describe one form of destructor, as the principle of the various types is not very widely different.

The destructor is essentially a sloping hearth with fire-bars towards the front. The refuse is tipped in at the back, and the hot gases from the hotter portions in the front pass over and dry it. It then gradually feeds into the hotter portions of the furnace and is completely burnt. The clinker is removed from special doors in the front. The method of charging these furnaces is responsible for the heavy costs for repairs, and many attempts have been made to apply automatic stokers, but they have not met with any large measure of success. An arrangement brought out by Mr. H. P. Boulnois, engineer to the Liverpool Corporation, dispenses with the handling of the refuse. This consists of a waggon 5 feet wide, 3 feet deep and any convenient length, which is divided into compartments, each being the full width of the waggon, and contains sufficient for one charge. Each compartment has a door, which is held in position by a pulley running on a third rail, and when the door into the destructor drying-hearth is opened the portion of the third rail on which the pulley runs moves away with it, the door in the waggon is opened, and the refuse falls on the hearth. The destructor door is actuated from the front. Thus the dust is never handled in the destructor station, as it is shot direct from the carts into the waggon.

It is found that a destructor worked on the drying-hearth principle is usually a nuisance. Dust and fumes come out of the chimney, the decaying matter being really destructively distilled as well as being dried in the process, and the large draught required blows the dust up the chimney, to be deposited on the surrounding houses, &c. To obviate this difficulty Mr. Jones, borough surveyor of Ealing, devised the "fume cremator," which is a separate furnace placed between the destructor and the chimney. It consists of a furnace having a reverberatory arch, with rings of fire-bricks projecting, which deflect the gases and directs them on the top of a red-hot mass of fire. An intense heat of from 1,000 to 1,500 deg. Fahr. is maintained at little expense, the fuel being ashes screened from the refuse and fine coke breeze. A supply of air is provided under the fire-bars, and a further supply of air is mixed with the gases as they enter the cremator. The contact between these gases, the fire-brick furnace and the red-hot fuel completes the combustion of the gases and dust, and it is found that the nuisance before mentioned is prevented. It may be urged that the cost of keeping the cremator going adds considerably to the expense of the destruction; but when the heat of the refuse is used for steam raising, this "cremator" is made the boiler fire-grate, and the fuel is not wasted in the least.

It is now my object to show how far the heat from the destructor is utilisable for electric supply, and in the first place it is to be ascertained how much heat may be obtained from 1 lb. of refuse, and the ratio of refuse produced to population and the ratio of population to 8 candle-power lamps required.

At Birmingham 179 lbs. of water have been evaporated per lb. of refuse, and at Oldham 138 lb. of water per lb. of refuse. The anticipated results are usually much higher than the realised, and Mr. T. Tomlinson, B.E., gives as a fair result from his own inquiries and tests that from 500 lbs. to 800 lbs. of

water can be evaporated per ton of refuse when burnt without sorting out anything except bottles, cans, &c., which fetch a fair price for other purposes. In fact, the quality of the refuse varies very considerably.

It is usually taken that 4 cwt. per head per annum is a fair figure for the production of refuse. This means that in a town each person will provide enough refuse to evaporate from 100 to 160 lbs. of water per annum.

Taking a town of 10,000 inhabitants, the quantity of water evaporated will therefore be 1,000,000 to 1,600,000 lbs. We will take it as 1,300,000 as an average. The demand which could be expected for some years to come will not be more than the equivalent of 6,000 8 candle-power lamps, and it is taken that the average consumption is 16 units per lamp per annum, that is to say, assuming 50 lbs. of water per unit are required all the year round, the water required to supply this is  $16 \times 50 \times 6,000 = 4,800,000$  lbs. It has been made out by many people that the refuse will supply *all* the power required, but in such cases high evaporative powers have been assumed. In districts such as Shoreditch, where cabinet-makers abound, no doubt such a high result can be attained, or in coal districts where coal is cheap and is wasted; but in the ordinary town I think that the result taken, *i.e.* just under one-third, is about the one that could be expected.

It will be noted that one-third of the power can be obtained from the destructor; this is an item to be considered, and if too much expense and labour is not entailed it may be worth while to use refuse. It is absolutely necessary, however, that it be burnt very regularly, in fact, day and night continuously, and if the load on a central station were fairly uniform there would be no great difficulty. But unfortunately this is not the case; the demand in the daytime and early morning is very low and the evening load is high, also the winter load is heavy and the summer load light. This unevenness in the demand must be met and smoothed over as regards the refuse-destructor supply of steam.

In many stations where an alternating current system is in use the day load is fairly heavy, because of the energy wasted in the transformers, which is constant day and night, summer and winter, and it may be taken that the destructors will supply this load, and there is no need of storage. The day and night load required by the exciting dynamos used for providing current to magnetise the alternators can also be run as well from these destructors by means of low-pressure engines if there is any difficulty in obtaining a high pressure in the destructor boilers. The use of electric accumulators with the exciting circuit is to be recommended, and the whole of the excitation for the evening load may possibly be supplied. In fact, it is in the alternating current station that the refuse-destructor and electric supply will combine most readily, owing to the necessity for continuous running and attendance.

When we turn to the continuous current station the problem becomes really difficult. It is the boast of some central station engineers that they lock up their station at midnight and do not appear again until after midday in the winter and in the summer 6 P.M. These engineers would view with great disfavour the proposition that two shifts of men should be provided to attend to the storage of the electricity generated by the steam obtained from the destructor boilers from 12 P.M. till the next evening. In fact, it certainly would not pay, as the saving in the coal bill would never equal the interest on capital of accumulators and the extra wages. It is necessary that there should be an automatic storage of the energy.

A method which is now being adopted is that of storing the energy in water, and is the invention of Mr. Druit Halpin.

There are two distinct forms of this storage—feed storage and steam storage.

**Feed Storage.**—If the boilers are worked under practically atmospheric pressure, and are capable of evaporating 1,300,000 lbs. of water per year, which is the average taken, and if this steam is passed into tanks of cold feed water, the heat can be stored. The total heat in 1 lb. steam at atmospheric pressure is 1,178 British thermal units.

If this is allowed to condense (by mixing with water) it will give off  $1178 - 212 = 966$  heat units, which will heat up a further  $\frac{966}{212 - 60} = 6.3$  lbs. of water to 212 deg. F. from 60° F.

This, added to the 1 lb. of condensed steam, provides 7.3 lbs. of hot feed water. The process can be carried on fairly efficiently by lagging the tanks. Taking the efficiency to be 80 per cent., 5.8 to 6 lbs. of feed water are provided. In the case taken there are required 4,800,000 lbs. of water per annum.

The 1,300,000 lbs. of water will provide  $1,300,000 \times 5.8 = 7,540,000$  lbs., or sufficient power is being given in any day to heat the feed for the heaviest winter demand (nearly double the average for the year). Thus it will be seen that even supposing some steam to be used for driving mechanical fire-bars, &c., in the destructor building, there will be sufficient steam to provide hot feed for every requirement of the station. The advantages to be gained by this method are:—(1) The carbonates are deposited from the hard feed water into the hot tanks and help

to lag them, and also keep the boilers clean; (2) the use of economisers is not necessary, and water-tube boilers (which are admittedly the most suitable for central stations and do not require economisers) can be used; (3) condensing plant is possible, with a large reduction in the coal bill; (4) the water from the condenser need not be used again, with a good result as regards the boiler; (5) the storage is automatic. The expense of these tanks is not very high, as they are little larger than are needed to insure continuity of supply in case of accident to water mains. This method of storage is being used at Shoreditch, except that the water is further heated to the actual temperature from which it is to be evaporated, *i.e.* it is put under pressure, the same pressure as that at which the boilers work. The water is pumped into these tanks cold, and the feed is gravitational. In the case where the water is under atmospheric pressure, the water has to be pumped into the boiler hot, but there is a considerable saving in capital expenditure on the tanks.

**The Steam Storage System.**—In this system the boilers are worked at a much higher pressure than that at which the engines work for, say, 16 hours per diem. The usual pressure being, say, 115 lbs. per square inch, the day pressure is, say, 250 lbs. per square inch. Drums containing water are connected to these destructor boilers and absorb the steam until the water is at the same temperature as that in the boiler, in fact, the temperature corresponding to the pressure. The amount of steam absorbed is easily calculated.

Suppose water at 115 lbs. per square inch connected to a steam main. The temperature at 115 lbs. is 347 deg. Fahr., at 250 lbs. it is 406 deg. Fahr. Thus the range of temperature is  $406 - 347 = 59$  deg. Fahr. The heat required to raise the water through this temperature is 59 heat units per lb. Suppose that  $\frac{1,300,000}{365}$  lbs. of steam are available at an average of 205 lbs.

per square inch per day, then two-thirds of this are available for storage heating per diem, *i.e.*  $\frac{2}{3} \times \frac{1,300,000}{365}$  lbs. of steam. Thus 2,374 lbs. of steam can be condensed, *i.e.* multiplying this by the latent heat 873, we get the heat units available, and this will heat  $\frac{2,374 \times 873}{59}$  lbs., *i.e.* 18,178 lbs. of water must be

provided to store the energy, or about 290 cubic feet. This 2,374 lbs. of steam, less waste, say, 12 per cent., or 2,000 lbs., will of course be recovered from the drum if the pressure is lowered to 115 lbs. per square inch. The 2,000 lbs. of steam will at this heavy time run an average of  $\frac{2,000}{8 \times 30}$ . Taking

30 lbs. of steam per horse-power hour, and eight hours' run = 8 horse-power for eight hours = 64 horse-power hours, the boilers themselves being capable of giving  $\frac{2,374}{2} = 1,187$  lbs. of steam, or  $\frac{1,187}{8 \times 30} = 4.9$  horse-power, or in other words there

are available 68.9 horse-power in any one hour, with 4.9 horse-power for the rest of the eight hours, or an average of 103.2 horse-power hours in this manner by storing the energy in 290 cubic feet of water during light load of sixteen hours. If, however, the heavy load is not so long the maximum power available for an hour is more.

In many cases the water in these drums is used for feed purposes as well, in which case more heat is capable of absorption in a less quantity of water. For instance, taking the 2,374 lbs. of available steam in the sixteen hours under the same conditions. Then if the water is 60 deg. Fahr. in the drum at the commencement, and let  $x$  lbs. of water be present, the range of temperature is  $406 - 60 = 346^\circ$  and  $x \times 346$  heat units are absorbed in heating this up to the temperature of steam at 250 lbs. per square inch, *i.e.* 406 deg. Fahr.; consequently,

$$x = \frac{2,374 \times 873}{346} = 5,990 \text{ lbs.}$$

The heat given out when the pressure is let down again, and the whole of the water has been used for feed purposes, is of course the same, but its distribution is different, the large portion being given back to the boilers as feed water, enabling them to do more work, and the balance as steam to the mains; but the result is the same as regards horse-power hours, *i.e.* 64 horse-power hours in this case. The reduction in the size of boiler made possible is very great, and consequently the less capital outlay is quite sufficient, and more than sufficient, to pay for the drums in a storage system, so the total capital outlay is less in a large plant and about the same in a small one.

As a matter of fact, it must be remembered that there is no reduction in the size of engines. For instance, a tank to store 75,000 lbs. of water will cost 600*l*.

$$\text{Water} = \frac{\text{steam supplied} \times \text{latent heat}}{\text{range of temperature}}$$

$$75,000 = \frac{S \times 873}{346}; S = \frac{75,000 \times 346}{873}$$

$S = 28,590$  lbs.; *i.e.* say, 714.7 units of electricity, allowing 40 lbs. per unit, can be stored for a capital cost of 600*l*. Now, an electric accumulator battery cannot be got for this sum, but it must be remembered that in the case of steam storage the engines and dynamos have to be the same as if the storage were not used.

Assuming the capital cost of this storage to be 600*l*., it is evident that the cost of accumulators, less the cost of extra dynamos and engines required, will be the equivalent cost of accumulators. The maximum load would be about 280 kilowatts. If the battery is to store 714.7 units, the dynamo power would be (assuming 18 hours charging and 60 per cent. efficiency between steam and discharge from accumulator) approximately 80 kilowatts. Such a battery would cost 3,740*l*.

Thus with accumulators two 80 kilowatt dynamos and engines would suffice costing 3,000*l*. With steam storage five 70 kilowatt dynamos and engines would be wanted (allowing dynamo reserve in each case), costing 6,500*l*. + 600*l*. for storage.

Allowing nothing for smaller buildings, the difference would be 7,100*l*. - (3,740 + 3,000) = 360*l*. in favour of accumulators.

As regards working expenses, as before mentioned, the accumulators would need two new shifts to be formed in the continuous current central station, while the steam storage would not. The successive drums could be turned on by the destructor stokers when they found the steam pressure rising above 250 lbs. per square inch.

A good method would be to have steam storage for the shift midnight to 8 A.M., and accumulators for the day, as there is usually some one present then, and also for filling up the load factor of the engines in the evening, and this would probably work out to be the most economical in the end, taking everything into consideration.

No one would dream of using accumulators or even storage drums to any great extent at the present time for central-station work, unless a constant supply of power, otherwise wasted, is available. The cost of these storage arrangements is rather high, and the trouble and expense of working is certainly higher, while they introduce an element of risk.

The coal bill in a continuous current central station is usually not very large compared with wages, standing charges, &c.; but if central stations are found to cost as little to work when refuse-destructors are employed as they would have cost without, there is no doubt that refuse-destructors will be combined with the continuous current central station boilers and the cost of disposing of the refuse saved. Figures are required as to the total saving to the local authorities found by adopting these destructors, (1) Not utilising the destructors for steam-raising, (2) utilising them for this purpose, then an opinion will be possible. In any case the quality of the refuse will be the determining factor.

To sum up. In a fairly small town, with an average quality of refuse, the steam available is sufficient, by utilisation of storage, to supply about one-third of the ultimate probable demand for light. That with an alternating current station great economy can be effected by the use of this steam, without any great storage or capital outlay; but that with continuous current stations the advantage is extremely problematical, unless more than one-third of the steam required can be obtained. It is also shown that feed storage is advisable, and that the feed need not be at more than atmospheric pressure to get a good economy. That the steam and feed storage combination is the most economical as regards water required, and that the ultimate capital cost is more than if accumulators are used, especially if cost of buildings, steam mains, &c., is taken into consideration. That at present an engineer would not recommend steam or feed storage unless dust-destructors were combined with them.

## ADVANCEMENT IN ART.

A LECTURE on "Sixty Years Advancement in the Fine Arts" was delivered by Mr. Herkomer, R.A., at the Crystal Palace. He said that, to his thinking, the characteristic changes that had been brought about could be broadly defined as, first, the development and destruction of the art of wood-engraving; secondly, the development of the art of water-colour painting to the highest capabilities of the material; and, thirdly, the change of front in the type of work from one essentially English, evolved by English painters of England, to one of foreign tendency. The development of any reproduction was stimulated, if not entirely brought about, by the requirements of the artist who did the original work. Having traced the history of wood-engraving as applied to illustrated newspapers, Mr. Herkomer reminded his hearers that in 1840 Sir John Gilbert, the father of all illustrative work, stood aghast when the late Mr. Ingram suggested the production of a weekly illustrated newspaper; yet to-day we had about 1,000 illustrated journals. With regard to the development of water-colour painting in the Victorian era, he would not touch upon such events as the pre-Raphaelite movement, or speak of Millais, who raised the whole status of English

art, or of Leighton, who raised the status of the artist. The most striking episode in this particular department was the advent of Frederick Walker. The so-called Walker school was made patent by the genius of a rare artist who died at an early age in 1875. He had many enthusiastic followers, but of those very few were left. "The Walker craze is over"—thus spoke a picture-dealer the other day. Although only twenty-two years had elapsed since his death, there was to-day only one in five that knew his work, and only one in twenty that really loved it. Yet the Walker period was a great period in the Victorian era. Mr. Herkomer next imagined a delightful picture of English country scenery, and went on to say that England to all goodly persons must appear lovable; that being so, they might surmise that that very loveliness would be a form of beauty that would never be neglected. We had, however, studied too much of French art, and had not even succeeded in welding the good qualities of those good paintings on to English nature. Why should painters try to play golf on canvas by getting into a hole with as few strokes as possible? It was cruel to strike at the chord of art in that way, and crueller still to malign England by such practices. Let them cherish their England, their cottage homes, farmsteads, village greens and shady lanes, and let their painters and poets paint and write in order to keep those treasures warm in their hearts.

### UNSUCCESSFUL ARTISTS.

ON Saturday evening the Bishop of London presided at the annual dinner of the Artists' Benevolent Institution. In proposing "Prosperity to the Artists' General Benevolent Institution," his lordship said that doubtless most of those present thought the best form of prosperity which the Society in whose interests they were gathered could attain would be that it should cease to exist, because the cause which had brought it into being should have ceased to exist. But until that ideal state of things arose—and he was afraid it was not likely to arise in our time—they could only moralise on the causes of human failure and human success, and admit that they were entirely beyond their capacity for calculating. He remembered once talking with a brother bishop about a man for whom they wanted to do something. They spoke at length about his virtues, they detailed his good qualities and considered what he could do and what could be done for him. At last his friend heaved a deep sigh and said, "He is as good as gold and he will go to heaven, but he is no use." He spoke from the conviction which had long been at the bottom of both their minds, but which they did not like to confess to one another. In olden times there was proper provision made for persons of that kind. There were monasteries to which they could retire, and if they were artists they could spend their time in decorating the walls of the cloisters with frescoes or in illuminating missals. But now the rise and development of modern society had swept away such admirable retreats, so necessary for a considerable part of the population and had substituted the less picturesque and, he regretted to say, the less popular institution of the workhouse. It was impossible for them to discover the causes that made for success or failure, and those present who had succeeded must very often wonder why they had done so, and must sometimes, in a cynical mood, think that the public taste was very incapable of proper discrimination. They must feel that there were many of the acquaintances of their youth who were really much better fellows and who could do much better work in a great many ways, but who, somehow or other, had not succeeded, and who, it was felt, might have succeeded if they had had their due. In all classes and in every pursuit they had the same feelings, but it had to be admitted that to artists those considerations particularly applied. First of all, the artist had to choose his career at a very early period, and he might do so, perhaps, on the inadequate grounds that he had a nice turn for drawing and a keen eye for the beauties of nature and of man. No one could foretell in what direction or to what degree those qualities would develop as he grew older. A poet who failed in outdoing Homer had, at all events, an opportunity of sinking back into a second-rate journalist. An artist was debarred from any such consolation. There was, indeed, very little for an unsuccessful artist to fall back upon. It was true he could do a little in the way of illustrating the daily papers, but not everybody who had art in his soul had capacity for that form of it. The nature of the artist's training was somewhat exclusive, and if he filled a mighty canvas by which he hoped to outlive Titian and did not succeed in that purpose—and he rarely did—the canvas was of no particular use. He could not even scrape the paint off and use it again. If he devised a statue which was to convulse the world, and only succeeded in convulsing the marble of which it was made, he found a hopeless difficulty in disposing of it, because nowadays, as the fashion went, people

did not care to put up statues even in their gardens. The unsuccessful artist could, indeed, fall back on little. It was more and more difficult even to sink back to the comparatively humble position of a teacher of drawing, for South Kensington now produced its young men adapted to that purpose. Nowadays, too, the public taste was so difficult to foresee that no one could venture to say who would be a success or failure. No one could say what would hit the public taste, all was a matter of chance. It was the object of this institution to rescue the unsuccessful artists from the most pitiable distress and to try to tide them over a bad year in the hope that better success might befall them in the future. Last year he saw that nearly 4,000*l.* was raised and spent in the relief of indigent artists. That sum was used for relief in nearly 250 cases. Such a work as that was one upon which they were to be congratulated and of which they might be justly proud.

The Chairman subsequently gave the toast of "The Artistic Societies," Sir E. Poynter, Sir Seymour Haden, Mr. Wimperis, Mr. Wyke Bayliss and Professor Herkomer responding. After the toast of "The Chairman," which was proposed by Lord Davey, Mr. W. Oules, R.A. (honorary treasurer), announced a list of subscriptions and donations amounting to nearly 2,000*l.*

### THE GREEK THEATRE.

AT the Royal Institution, Albemarle Street, on Saturday, Dr. J. P. Mahaffy delivered the second of his course of three lectures on "The Greek Theatre according to Recent Discoveries." A closer examination of the remains of the Athenian theatre discovered in 1862 was entered upon, and the evidences which they afforded of various ages explained. Describing the simple, rude theatre in which the great masterpieces of Æschylus, Sophocles and Euripides were performed, the lecturer remarked that the spectators sat in rising tiers on wooden benches; they had no protection from the sun or rain; the actors and chorus played below them on the orchestra in front of a temporary wooden and painted background. It seemed natural at first sight to suppose that the actors should be in some way separated from the rest and play on a higher level. That some temporary platform was stationed in front of the scene was not impossible, but from the evidence now accumulating very improbable. There were many good reasons for assuming that there was an altar in the centre of the orchestra and that the earliest actors had the altar steps from which to speak. The construction of all Greek theatres, seating spectators round more than a half circle, implied that the main point of interest was not at the chord joining the end of the horseshoe, where a stage might be expected, but well in front of this and on the east of the orchestra. The theatre at Athens was not merely enlarged or improved; it was wholly rebuilt during the fourth century B.C. As regarded the performance, when high tragedy went out of fashion genteel comedy, with its middle-class society, simple appointments and its absence of dramatic excitement took its place. There was the same kind of contrast as between the novels of Miss Austen and Mrs. Gaskell and the romances of Walter Scott and Bulwer Lytton. For these performances there was only required a shallow acting ground with a back scene capable of some small changes. The actors, who at first were only distinguished from the chorus by standing on the steps of the central altar, afterwards assumed high boots, masks and other devices.

### GLASGOW ARCHITECTURAL ASSOCIATION.

AT a meeting of this Association held in the rooms 187 Pitt Street, on Tuesday, the 4th inst., Mr. Geo. S. Hill, vice-president, in the chair, Mr. W. J. Anderson read a paper on the "Acropolis of Athens in the light of Recent Researches." The essayist, in the first place, showed the kinship of the primitive Acropolis of Troy, Tiryns, Mycenæ and Athens, and the indications at Athens of the pre-Homeric era, to be superseded by that of Hellenic Greece. The buildings of this period were severally considered in their purpose: the ancient temple of Athene Polias, the Parthenon of Pericles, the entrance gates of Propylæa, the megaron of Erechtheus, and his museum or heroon. The present aspect of the buildings, their architectural details, and their former magnificence were shown by a large number of lantern views and restorations. On the motion of Mr. Alexander McGibbon, a hearty vote of thanks was accorded to the essayist.

Mr. C. P. Ayres, of Watford, Herts, architect and surveyor, has been elected chairman of the Watford Urban District Council, and has been duly sworn in as a magistrate for the county.

## NOTES AND COMMENTS.

It will be remembered that in April 1895 there was a loss of life and property in the district of Bouzey, department of Vosges, in the east of France, owing to the failure of a reservoir embankment. An inquiry into the question of responsibility has been in progress from that time. The commission considered that a charge of homicide through imprudence could be brought against the engineer-in-chief of the department and three other engineers. The trial is being held at Epinal. The experts are of opinion that the cause of the accident was the defective construction of the embankment; but as the period of three years, which is the limit of responsibility for works of the kind, had elapsed prior to the catastrophe, the contractors could not be held responsible. The engineers, it is thought, should have detected the weakness at an earlier time. In no country is there more careful construction than in England, and yet the destruction of reservoir embankments is not an unknown phenomenon in English engineering. Imperceptible leakage may be weakening a bank or wall for a long period, although supervision is constant.

ALTHOUGH the death of the DUC D'AUMALE was sudden, the Institut de France was prepared for the contingency, having to take possession of Chantilly and its treasures on a short notice. Ten years ago, when the property was offered to the nation, the Conseil d'Etat made it a condition that a detailed inventory should be prepared. That work was done, and it can be tested by the special catalogues of the different departments, which were made out by the prince's officers. A few of his later acquisitions, such as the miniatures by FOUQUET, which cost 12,000*l.*, may have to be added, but that is an easy task. It will be necessary to appoint a staff to take charge of Chantilly. There is little doubt that M. DAUMET, who has had charge of the restoration, will be entrusted with the conservation of the buildings. The authorities will have to consider a problem similar to that now before the committee of inquiry into the adaptation of Sir RICHARD WALLACE'S house. It is not likely that Chantilly will be transformed into a museum, but will be allowed to remain as a château of a remarkable kind. But provision will have to be made for the exhibition of drawings which are now in portfolios, and of bijoux which are in closed cabinets. There may be appointments for scholars in the buildings, but only experts will be able to make the woods and lands yield a profit. It is calculated that 12,000*l.* a year was obtained by the Duc D'AUMALE, and the expenses are not unlikely to need that amount of money.

MANY theories have been formulated to explain the peculiarities of the ancient crosses which are found in Great Britain and Ireland, to which the Isle of Man may be added. The latest was explained in a paper which was read in Edinburgh on Monday by Mr. ROMILLY ALLEN, an archæologist who has devoted much of his attention to the subject. Referring to the peculiar style of decoration of the period known as Celtic, which was by some assumed to have had its origin in Ireland, Mr. ROMILLY ALLEN said it was no doubt true that Celtic art attained its highest excellence in Irish illuminated manuscripts, such as the Books of Kells, Armagh and Durrow; but it was a relevant inquiry to what extent the illuminators were indebted to foreign sources, and whether the similarities of design on the monuments of the eighth to the eleventh centuries in Scotland, Ireland, England and Wales might not be accounted for by development on parallel lines rather than by direct derivation. Instancing a series of rubbings taken by Mr. GRIFFITH-DAVIES from cross-shafts and fragments at Clonmacnoise, which closely resembled the slabs of Perthshire and Forfarshire, he proceeded to point out other resemblances between the Irish and the Scottish monuments generally, alike in their decoration and in the groups of Scriptural figure-subjects which appear on both. The Irish crosses are chiefly found in Leinster and Ulster, and are absent from the counties of Kerry, Cork and Waterford, which contain the ogham-inscribed pillar stones of the earliest Christian period, and the total number of crosses in Ireland, amounting to about fifty, was extremely small as compared with the 300 localities in Scotland, 250 in

England, 40 in Wales and 15 in the Isle of Man that were now on record. The conclusion seemed to be that the pre-Norman crosses of Ireland were later than those of Scotland, England and Wales, and that this phase of early Christian sculpture had its origin in Northumbria. The scrolls of foliage on the Irish crosses and the bird and leaf motives in the Book of Kells indicated Northumbrian influence. Scandinavian influence had not been detected on the Irish crosses, but was found on the metal-work. In conclusion, he considered that the Celtic style was a variety of the Lombardo-Byzantine style, from which its figure subjects, interlaced work, scrolls of foliage and many of its non-descript animals were obviously derived.

THERE can be no doubt that Mr. W. D. CARÖE'S evidence produced an effect on the Select Committee of the House of Commons and aided in enabling the members to arrive at the unanimous conclusion that the preamble of the County Council's Bill, so far as it related to the proposed embankment at Cheyne Walk, was not proved. A petition against the scheme was signed by Sir E. J. POYNTER, Mr. A. WATERHOUSE, Mr. BRITON RIVIÈRE, Professor AITCHISON and other artists. There were two great objections to the Bill. In the first place it introduced the principle of betterment, which cannot be said to have received universal approval; and, secondly, one of the few remaining views in the Metropolis that could be called picturesque was likely to be blotted out. The allegations about the insanitary conditions of the foreshore must also have appeared questionable to the members of the committee. They know that tests have been repeatedly applied, and it still remains uncertain whether there is any increase of danger to life from residence on a river bank. There may be occasionally sights and odours which are disagreeable, but there seems to be compensatory influences which keep the death-rate from increasing.

## ILLUSTRATIONS.

CLARIDGE'S HOTEL.

THIS illustration, which is reproduced from a drawing in the Royal Academy, shows the treatment of parts of the new hotel in Brook Street, the interior being designed by Messrs. ERNEST GEORGE & YEATES. The structure is practically complete, but the lofty ground floor, with its "winter garden" and reception-rooms, has been carried out with iron stanchions and girders, and was left for future development.

The large coffee and dining-rooms, separated by a screen, are to be arcaded, as shown in the drawing, with oak panelling and intarsia up to the springing of the arches. A stone chimney and beamed ceiling of the smoking-room is shown in the drawing.

49 PRINCE'S GATE.

THIS house, which contains the well-known "Peacock Room" adorned by Mr. WHISTLER, has been undergoing changes for Mrs. WATNEY. The drawing shows a range of windows in the music-room, the arcaded treatment giving a deep sill for palms, &c. The woodwork of this room is of walnut.

The oak panelling of the dining-room is also shown, and the fine old leather of the walls.

The hall, with its flatly-carved stone pilasters and intarsia doors, is not here shown, but it is the most important of Messrs. ERNEST GEORGE & YEATES'S late introductions to this house.

The work has been well carried out by Messrs. TROLLOPE & SONS.

VILLAGE OF BUSCOT, BERKS.

A DIFFERENT example of work from the same hands is a "parish-room," cottages and farmhouse, at Buscot, for Mr. ALEXANDER HENDERSON, who is also giving the oak lych-gate to the parish church.

This is part of a group of pleasant stone cottages, with their stone roofs that harmonise with the old work, in a beautiful corner of Berkshire. Mr. BEWLEY, of Lechlade, has carried out these buildings very satisfactorily.

The architects are Messrs. ERNEST GEORGE & YEATES.

## NORWICH CATHEDRAL.—II.

THE nave of Norwich Cathedral is divided in its length into fourteen compartments on each side, and built upon as many semicircular arches, of great solidity and depth, and supported by piers of the same description, excepting in two instances, where instead of piers are placed two cylindrical columns of vast thickness, ornamented with spiral flutings, one on each side of the nave and opposite each other. The arches of the nave have a few plain and very bold surfaces, and the outer one of all is adorned with a billet moulding. The triforium is of great and very unusual height; it is composed of arches and piers very similar to those on which they stand, and nearly the same height. This arcade is entirely open, and is not, as is commonly the case, subdivided in each arch by a single pillar supporting two smaller arches within the greater. The outermost surface of the arches is adorned with the zigzag moulding; the arcade above this is unusually low, formed by three semicircular arches, side by side, in each of the compartments of the nave, with very simple mouldings resting on short cylindrical columns, the middle arch being of three times the span of the outer ones, and through which are seen the windows of the clerestory. These windows are plainly the insertion of more modern times; the original window was round-headed, wide, and of one light; the round head has been walled up, and an obtusely pointed arch introduced beneath it, and the window divided into two lights by a plain mullion with corresponding tracery in the head of it. The roof of the nave is magnificent both in its design and extent, for though the choir obtrudes itself into the nave as far as the two first compartments eastward, this arrangement does not interfere with the vaulting, which is seen in all its length from the west window to the central tower. The roof was constructed between 1450 and 1472, during the episcopate of Walter Lyhart, whose rebus is introduced in the work. Had this vaulting been erected a century earlier it might have agreed better with the architecture of the nave, but in itself it is a beautiful work, and rich though it be, and elaborate in its design, it does not injure the effect of the whole. The side aisles of the nave are in their original state; the vaulting of them is plain and ponderous; it is semicircular, without any mouldings, or ribs, or carved keystones.

The transept is intercepted by the choir, which is partly under the central tower and stretches beyond it, as we have before observed, into the nave itself. When the choir screen was altered it would have been better to have removed it to the eastern arch of the tower, that the transept with its lantern might have been seen at once in its length and breadth and in connection with the nave. This portion of the cathedral is also original; it is singular in having no side aisles; it is of good length, rather deficient in breadth, but of the same height with the nave and choir, and like them elegantly and richly vaulted with stone.

The effect of the choir on first entering it is very imposing; coming across the transept, and into the nave, it is of unusual length. The lantern is set upon four semicircular arches with plain mouldings, and supported by four massive piers of the same plain, solid description. The first horizontal compartment above these arches is an arcade of semicircular arches resting on short cylindrical columns, behind which is an open gallery all round the lantern. The next compartment is adorned with a similar arcade, without the accompanying gallery, but it does not extend the whole length of each side, instead of which the spaces on each side of every one of the four arcades are pierced with a circle with a plain moulding round it; the third and highest compartment consists of a lofty arcade with semicircular arches, and of a complicated and curious character. This arcade has also behind it an open gallery all round. Immediately above this is a flat ceiling of stucco-work, with cornice and panels, adorned with wreaths and medallions, very good in its way, but we need hardly say totally out of place here, and spoiling the whole effect of the lantern.

The clerestory of the choir is of a totally different age and style, and yet the effect of the whole is exceedingly good. The windows are pointed, well proportioned of four lights each, with good tracery in their heads. Between the windows on both sides are lofty deep niches feathered and canopied, which doubtless once had statues. From the top of these niches spring the main ribs of the vaulting, which is similar to that of the nave and transept. The windows in the clerestory of the apse are of the same size and character with those on each side of the choir, but they are so close to each other that there is no room for anything between them but a cluster of three slender shafts, on the top of which spring the ribs of the groined roof of the apse, which is well designed and has the most charming effect. Indeed this part of the clerestory is very cleverly set upon the triforium of the apse, which is semicircular, while this is pentagonal. The lofty, wide and open triforium of this cathedral, both in the nave and choir, has a very majestic and imposing effect throughout, but more

especially in the apse where the arches are of less span and nearer together.

The side aisles of the choir are of the same age and style with those of the nave, and vaulted in the same plain and ponderous manner. In the side aisle to the south is the entrance into what was Bishop Beauchamp's chapel, a small oblong room with, groined roof, and a large window of decorated character opposite the entrance. A little further on at the south-western extremity of the apse is the entrance into what was St. Luke's Chapel. At the north-western extremity of the apse is placed the entrance to another chapel very similar to that of St. Luke, and dedicated to our Saviour, and in the middle of it is the tomb of Sir Thomas Windham.

## VILLAGE CHURCHES.

THE following paper was written by the late G. G. Scott, M.A., many years ago, and must now have some interest as an exposition of his principles respecting one important class of buildings:—

There is, as far as I know, no country in Europe where the village has retained so much of its primitive importance as England. Nowhere has the influence of the great towns been, until quite recently, so little felt. The Englishman is, after all, essentially a countryman, and country life is not more the birthright of the gentleman than it is the aspiration of the successful man of business. It is not, therefore, unnatural that our village churches should be the especial pride of our national architecture. Our cathedrals, with some noble exceptions, are surpassed by the great churches of continental cities. Our abbeys themselves, centres of agricultural life, which were once the glory of England, have passed away; but the village churches still remain, so far, at least, as the hand of the restorer has spared them, as the finest monuments of the architectural genius and the practical piety of the past generations of Englishmen.

The village is, next to the family, the simplest and least artificial of all the forms of social organisation, and it has continued through all the changes which religion and politics have undergone in the main unchanged.

It still consists essentially of the same elements which constituted the little primitive community from which it takes its origin, and it forms to this day, as it did at the first, the unit of all political association.

The village church has besides a peculiar interest of its own. It is the only public building which a village, as a rule, possesses. It is the central point of the common life, the building which typifies the oneness of the little community. Cities have beside their great churches or their cathedral, their town halls, their market halls, their assize courts, their theatres, all connected in different ways with the common life to which they minister and which they symbolise; but the village has only its church and its churchyard. Here alone all meet on equal terms and with an equal right, as members of one little society of which the church forms naturally the centre.

## The Site.

These reflections may serve to invest our subject with a proper dignity. They are considerations which were never absent from the minds of those who first founded and erected our ancient parish churches. They are not always, I regret to say, so prominently in the minds of their successors; and this will lead us at once to a consideration of a very practical character, and one which is too much overlooked—I mean the great importance of the choice of site. The old builders placed their churches with wonderful skill. In the flattest, the least accentuated country, they always succeeded in giving their building something of character and importance from a judicious selection of the ground. They almost always found some little knoll, some slight elevation, which might give to the church an advantage worthy of its character and impart a certain amount of dignity to the simplest erection. This point is far too much neglected now. As a rule the architect, the man who ought to be able to judge of such matters, is not called in until the site has been secured, and he has then to make the best he can of it. The site is too often some useless corner which can be bought cheap or be presented without sacrifice. The architects, too, I am bound to say, fall in only too readily with such a system, and design their buildings as if every site was an absolute plane. Should the site possess a decided slope or any marked configuration, it is specified that the earth is to be removed from the elevated portions and deposited to fill up the lower ground. The building so erected has the effect of a toy church set down upon a little tray prepared for it. You feel that the designer would have set it down upon the level if he could, or you may very easily fancy that the whole thing has been bought as it stands from a wholesale dealer in ready-made churches.

The look of an old village church is something quite different; the building and the site here belong to each other, the church seems to grow upon the hill side or the knoll, grasping, as it were, the ground with its great buttresses, like the spreading roots of an old tree. You could not readily imagine it on any other site; it belongs to the place just as much as the aged yews which grow beside it. Much may be done by help of a well-chosen site, even with a poor building, and this is one point which I would urge especially upon those who do me the favour to listen to me to-day, because the choice of site rests in most cases with the promoters of church building, with the clergy and gentry, rather than with the architect. It is perfectly astonishing what a difference may be made by a judicious choice of site in the effect which a building will produce, and in no case is this so important as in village churches, where we have no imposing dimensions to give dignity of themselves, and where, nevertheless, the importance of the building, as the centre of the whole village, renders it necessary to give to it the utmost accentuation that we can.

#### *The Tower.*

From the same point of view the position of the tower is the next most important point. It may be broadly stated that almost all ancient towers are placed in the centre line of the church, almost all the modern ones at the side. It is quite an exception to see an ancient tower which does not stand either in the centre of the crossing or in the centre of the west front; it is quite an exception to see a modern tower which does not stand somewhere at the side of the chancel. The tower of a new church seems to be placed in some corner which is wanted for nothing else, as a pendant on plan to an organ-chamber or a heating apparatus. Of all positions for a tower, next to that of a proper central tower, the west-end position is the noblest; it has even some advantages over the central position, especially in the case of a small tower. I cannot conceive why a plan which gives dignity to the smallest church should have been so generally abandoned. I think that the centre of the west front might well be assumed as the normal position for the tower, only to be departed from where there is some manifest reason for doing so, founded on peculiarities of site, or some very special practical convenience. A west-end tower is comparatively easy to design; a west end without a tower is always difficult. It demands a great west window, and this floods the church with such a quantity of afternoon sunshine as no stained-glass can control. A central tower placed at the intersection of the transepts is seldom advisable in a village church, except where, from some peculiar circumstances, the monumental character takes precedence of the practical consideration of convenience. Yet that form of it which is frequently found in Normandy, where the tower stands over the chancel and the sanctuary proper lies east of it, is often very suitable and is always beautiful, if only one point be attended to—the eastern limb must not be too short. Indeed, our sanctuaries are generally made too short; they are too often cramped to the minimum which the bare necessities of administering the communion require, and even so the clergy, if there are several, have often great difficulty in avoiding an unseemly jostling. This and many other faults of our modern churches are encouraged, I am sorry to say, by the church building societies, and until they alter their system and give their grants on the total area of the churches, instead of on the number of fixed pews which can be squeezed into them, it is, I fear, useless to preach improvement in this respect. It is none the less our duty, as architects, to protest against a system to which, more perhaps than to anything else, the unsatisfactory character of our new churches is to be attributed.

#### *The Chancel.*

It may be laid down as a general rule that our modern chancels are too short for a well-proportioned architectural effect, as well as for the proper performance of the ceremonies, and it is certainly the worst possible policy to curtail them still further both in appearance and in actual area by adopting what is called the apsidal termination. I should be the last to deny the marvellous beauty of a complete chevet, with its procession path sweeping round it, and its radiating chapels leading up to a fine climax in the lady chapel. But there are several things to be borne in mind when one comes to the question of small apses. One is the great difficulty of roofing them satisfactorily. They really require groining. I do not think that even those French ones which have timber roofs are ever quite pleasing, and the attempts which have been made to accommodate English types of roofing to apses are, in my opinion, great failures. Then, again, you require very much greater height to give dignity to the interior. The great east windows of our English type may spring at the level of the roof eaves, and sweep up boldly into the gable; the highest point of the windows of the apse must be some way below the eaves. Unless, therefore, the height is very much greater, the effect has nothing like the dignity of the square end. The internal appearance, too, is always meagre where the light is admitted,

as it is necessarily in an apse with a wooden roof at a much lower level than that of the highest part of the interior. I know that considerations of artistic effect weigh but little with architects, who are thinking of the graceful sweep of their compasses upon the plan, and clients to whose ears "apse" and "apsidal" have a pretty ecclesiastical jingle; but I think the fact that you require greater height, and therefore greater expense, to produce an equal result ought at least to appeal to our common sense. It should further be remembered that in an apsidal chancel the apse must be in addition to the length, not in deduction of it. The chancel should most certainly be as long as a square-ended one, with the apse additional.

This follows clearly from the admitted principle that the altar should stand on the chord of the apse, and not against its circumference. Nothing, indeed, can well be more awkward than an altar placed up against a curved wall, giving the appearance of an afterthought clumsily introduced. Nothing can be much worse than this, while, on the other hand, nothing in its way is more dignified than the altar standing free upon the chord; but this, as I have said, renders it necessary to treat the apse as additional to the length which is required by a square-ended chancel. The continental apses are always so planned, and the neglect of this obvious principle is one cause of the inferiority of our recent attempts in this line to their foreign models. Only observe that here, too, as in the matter of height you must have more length and more expense to produce an equal result. The apse ordinarily used in our small modern churches may be described as an expensive method of producing a poor effect.

The square east end is the most marked peculiarity of our national church architecture. It is a tradition venerable, both from its antiquity and its singularity. It may almost be said that there are no square-ended churches except in Great Britain and Ireland, and none but square-ended churches here. The number of churches with square east ends throughout the whole of Christendom (excepting the British Isles) is exceedingly small. It is this fact that gives to the universal prevalence of this type in our own country its especial and unique importance. The tradition is carried back to a date earlier than the Middle Ages, by the small churches or oratories of Ireland, and the supposed British church of Peranzabulee. I think that the prevalence in these isles at that early date of a type of church different in a most significant manner from the types prevailing both in the Latin and Greek communions, is a most singular fact. It is the more remarkable when we consider to what a great extent the existing Christianity of England is due directly to the labours of Latin missionaries, who brought with them, as we know by the accounts of the first cathedral erected at Canterbury, the basilican plan with its apsidal end.

From the chapel at Peranzabulee, and from the square-ended early Irish churches, which, whatever be their date, certainly show little or nothing of the Latin influences, I think we must infer that the square east end was the prevalent type in these islands before the overthrow of British Christianity by the Saxons. We may conclude from this, as from other reasons, that British Christianity was not so utterly enfeebled as has often been represented, and that its own peculiar traditions survived and leavened to a considerable extent the great revival which the Latin missionaries effected. The square end tradition had a second great struggle for existence at the Conquest. The Normans naturally introduced the continental fashion, a fashion which the Confessor had already followed at Westminster Abbey. I think it probable that most of the Saxon churches which have apses date from his reign. The apse became almost everywhere the rule as long as the influence of the Norman clergy and nobility remained fresh and distinct; but no sooner had the conquerors begun to coalesce with the conquered, and the conquest become gradually tided over, than the square east end began slowly but steadily to gain upon its rival. By the thirteenth century its triumph was complete, and although we have in Westminster Abbey one of the most complete and beautiful specimens of the type in Christendom, the circumstance of its rebuilding and the French tastes of King Henry, render it clearly an exceptional case. It is a curious fact that the language spoken in that monastery was, as Abbot Ware tells us in his Customal, neither Latin nor English, but French.

A tradition so ancient and so remarkable, one peculiar to our branch of the Catholic Church, and connected in all probability with its very earliest origin, is deserving surely of all respect, and ought not to be abandoned to a mere feverish craving after novelty, or to the affectations of a travelled dilettanteism.

#### *Chancel Screens.*

Upon the same principle on which I have attempted to defend the square east end, I shall also venture to say a few words in favour of the high chancel screen. This essential feature of a Mediæval church cannot indeed be claimed as exclusively English; but we may boldly state that no Church

in Christendom has sustained the tradition so steadily and so continuously as the Anglican. It is a very curious fact that while at the Reformation the rood-loft—those galleries which spanned the chancel arches of the greater part of our churches—were destroyed, with the roods which surmounted them, especial care seems to have been taken to preserve the screen itself. This is, in itself, an interesting fact, as showing how orderly and methodical, as a rule, was the work of the Reformation, as compared with the Deformation carried out by the Puritans of the next century. Not only were the existing high screens carefully preserved, but many new ones were erected during the reigns of Elizabeth, James, and Charles I. A complete list of these does not, as far as I know, exist, and its want is to be regretted, as their erection throws great light upon the tone and character of the English Reformation. A learned living prelate upon one occasion stated to me, not I hope *ex cathedra*, that the use of a chancel arch was to distinguish exactly that part of the fabric of a church for the repairs of which the holder of the great tithes was responsible. I can hardly believe that this purpose alone will account for the erection of those rich Elizabethan and Jacobean screens which are the ornaments of not a few of our old churches. I do not believe that the spirit which could inspire such admirable work was of this dry practical kind. I think rather that the notion embodied in the rubric, "The chancels shall remain as they have done in times past," was a real and living principle. It has borne good fruit even in dry and sterile days, and in these more favoured times may be expected to blossom again with a renewed vigour. A tradition which has lived through the eighteenth century and produced many fine works, even in those dark days, ought not to be abandoned thoughtlessly and from mere caprice.

There are two distinct types of church arrangement answering to the two modes in which, in an ecclesiastical point of view, the eucharistic rite has been regarded. The one is primitive and Mediæval, the other is modern and Roman. The early and Mediæval idea is to withdraw the mysteries more or less from too curious eyes. The modern to parade them boldly before all. In the primitive church the altar was surmounted by a baldachin, the whole intention of which was to support curtains somewhat in the manner, if I may be excused the comparison, of a four-post bedstead, by which the act of consecration might be shrouded from the eyes of the faithful. The Eastern Church, so tenacious of early customs that it may be said even to exaggerate them, conceals the whole action by a solid iconostasis. The Mediæval ritualists, upon a similar principle, placed the altar withdrawn at the extremity of a long chancel, the entrance to which was fenced by a lofty lattice, which we call the high screen. It can, I think, hardly be questioned that this tradition has had an exceedingly strong influence upon the feelings of English churchmen, and it is still, in spite of vigorous attempts to supplant it by a newer development, the most firmly rooted and the deepest.

It ought at any rate to be clearly understood that the principle of screens is of the essence of Mediæval church architecture. Pugin somewhere lays it down that the man who says he likes Gothic architecture and does not approve of high screens is simply a liar. The expression is forcible, but true.

The whole notion of a Mediæval interior is that every vista should be broken up. You ought never to be able to see from end to end of a Gothic church. It is the greatest mistake in the world to throw our long churches open from end to end. The very effect that the old architects aimed at producing was to make you wish to see it all open, to stimulate imagination; but they knew very well the old truth that the half is better than the whole. The effect which a Mediæval interior is designed to produce may be compared to a sunset seen through trees; the glory of it makes you wish the trees away, and you hasten forward through the copse that you may gain the open and see the whole unbroken expanse of sky; but the effect is not what you expected; it has a charm, but it is not the same. You have gained a quiet placid enjoyment, but you have lost the keen, intense, exciting pleasure of the first view. In gaining a new delight you have lost the first, and perhaps the higher joy—you have, in fact, exchanged the Mediæval effect for the Classical. Now I might fairly plead that, if we are to build Gothic churches, we should build them on Mediæval principles, and should not attempt to confuse the characteristics of the two opposed poles of art. I might appeal to the many attempts which have been made to reconcile the two, and to their failure, but I prefer to take higher ground, and to rely upon the traditions of the English Church, in spite of its reformation. Perhaps because of it the English Church is the most Mediæval of all the Western Churches.

Dr. Neale has remarked in one of his essays that in no church in Christendom are the Mediæval offices so generally kept up. Nowhere else are so many hour services, essentially Mediæval, and even monastic in their origin, recited publicly as in England. One may add that, upon the whole, nowhere else have the choral arrangements of chancels been so carefully

preserved, through generations of opposition and indifference, as among ourselves, and it would be a matter of deep regret if traditions which have survived through years of general neglect and disuse should be abandoned in the turmoil and excitement of an almost unprecedented revival.

I do not, however, wish to lay down a rigorous rule, either as to the exclusion of apses or as to the absolute necessity of the high screen. There are, no doubt, cases in which an apse may be allowable enough, and we have in England, even in the advanced periods of Gothic architecture, many beautiful examples. I may mention Madely in Herefordshire, the Priory of Winchester, the chapel of the Holy Ghost at Basingstoke, and that of the Vine in the same neighbourhood. The High Church at Stirling is another example upon a larger scale. In most of these, however, the native love of the east window shows itself in the greater size of the eastern face of the apse, which allows of the insertion of a central window larger than those of the sides. These examples are very well deserving of study, and in exceptional cases may serve as models. In the same way, as regards screens, there are exceptions from the general rule; there are instances of low screens in some of our ancient churches, as at Nantwich, in Cheshire, and Chipping Norton, in Oxfordshire. In refitting an old church the high screen is, no doubt, more imperatively required than in a new building. In a new church convenience may often be allowed to override tradition.

There would be less objection artistically to a low screen if we were allowed to erect above it a rood-beam and a rood. By itself a low screen looks insignificant and wanting in dignity, and is but a very poor and enfeebled descendant of the iconostasis and the jubé. There is no doubt the chancel screens had, in all ages, a practical purpose—the protection of the chancel from thoughtless or profane intrusion. This, too, was the purpose of the introduction, under Archbishop Laud, of altar rails and gates. These were ordered to be sufficiently close to prevent the entrance into the sanctuary of dogs, which, if we may judge by pictures, were as frequently to be seen in English churches as they still are in some Highland kirks. We have almost abandoned the use of close and gated altar rails, and no one will regret the change, but this makes it only the more necessary to have an effectual fence at the chancel arch. It is not seemly to see, as one often does, the sanctuary invaded by a party of ladies and gentlemen, however ecclesiastical, criticising the reredos and handling curiously the embroidery of the frontal—bringing to mind the line which ends "where angels fear to tread." And the necessity of a proper fence to the chancel will become more felt as our churches become more used. I hope the day is not very far distant when it will be quite the exception to find a parish church locked up.

It is told of Thomas à Becket that when he was withdrawing into his cathedral, followed by the murderous band, the clang of whose armour was audible along the cloisters, a monk who was with him closed the door by which the Archbishop had entered the church and began to lock and bar it. St. Thomas stopped him at once. "The church," said he, "is not a castle; it shall never be barred upon my account," and ordered the bolts to be unfastened. Upon what trivial grounds, for what paltry considerations is that too generally done now which St. Thomas even in the extreme necessity of self-defence forbade. It is pleasing to observe that the number of churches, even in the country, which are habitually kept open is everywhere upon the increase, but it is certainly undesirable to leave the chancel and sanctuary wholly unprotected from careless intrusion or even worse. It is further to be hoped that the naves of churches may be made more and more serviceable for other purposes than those of direct worship. I was present upon one occasion at a missionary meeting held in the nave of Ely Cathedral. Everyone present must have felt that the surroundings gave a tone of dignity to the assembly, which a concert hall or the ball-room of an hotel would not have supplied, and if the education of this country should unfortunately become separated altogether from any true religious teaching, I do not think that anywhere else so well as in the naves of our churches could the children be assembled for that definitely Christian instruction which the public schools had ceased to supply. The influence of the place would go a long way to take off from the dryness of school work, and would be the best set-off against the disadvantage of the divorce of secular and religious education.

It is not at all uncommon in France and Italy to see churches so used. I remember seeing at Milan a very fine church occupied entirely on the Sunday afternoon by what we should call the Sunday school. The aisles were left open as usual, but the whole of the nave, which was very large, was curtained off into many compartments, which formed, in fact, separate classrooms. Under such circumstances it would be very necessary to keep the chancel and sanctuary distinct from the nave, and protected by effective and not merely symbolical cancelli.

In planning a new church the utmost freedom will properly

be allowed in the choice of the type which may be adopted, even to the extent of a rather wide departure from any of the ancient models, wherever new circumstances suggest new arrangements; for it is not so much the forms of our ancient architecture which we should seek to revive as its spirit. The one belongs to the age which produced it; the other is more or less for all time. We cannot, however, forego a careful study of our ancient models, a study to which the judicious architect will recur again and again to refresh the first keen impressions, which else, from contact with prevailing commonplace, become deadened and lost, and it is greatly to be regretted that the attention which is bestowed upon our old architecture is limited too often to a mere study of details. Sections of mouldings and patterns of traceries are noted down with some care and with some approach to correctness, but we do not, as a rule, take half enough account of the general scheme of design, of the distribution of the plan and of the general proportions. The consequence is that not only is it impossible to mistake, even at a distance, a new church for an old one—this, indeed, is not to be desired—but there is too often nothing at all akin to the effect of a Mediæval church, nothing of the spirit of the old work, nothing of that masterly power of outline, and that full and satisfying sense of proportion which even more than the details charm us in our old buildings. It is curious that some of the earliest works of the Gothic revival have much more of this quality than their more correct successors. With details which are often beneath criticism, some of these early attempts show an insight into the essential principles of Gothic design which is rarely seen now, and produce at a distance a much more satisfactory effect than many buildings of greater knowledge and of more pretension. Not to speak of such works as the towers of St. Peter's, Cornhill, and that of the parish church at Warwick, Highgate Church, and St. Luke's, Chelsea, may be instanced as good examples of what proportion and outline can do, unaided by any beauty or correctness of detail. I am afraid that the falling-off in this respect is to be attributed to some extent to Mr. Ruskin's architectural works, as well as to the unfortunate fashion which has introduced among us so many spurious imitations of French and even Italian Gothic. However this may be, I feel certain that much would be learnt from the intelligent study of the plans and proportions of our old churches, and that until the same attention is paid to the higher qualities of our Mediæval architecture which has been bestowed upon its smaller details, little advance will be made.

It must, I think, be admitted that the later styles show more power of dealing with proportion and mass than do the earlier, and perhaps purer, varieties; and this is especially true of small buildings such as are most of the country churches. With all the high qualities which the thirteenth-century work undoubtedly possesses, I still think that the style shows to the best advantage in buildings of a considerable scale, and that in smaller churches the later styles compare advantageously with those of the previous centuries. There is generally more facility and freedom in planning, a more artistic distribution of parts, and above all a greater economy of means. The early styles are rather wasteful; they require very massive walls. It is quite impossible, as sad experience has shown us, to get the effect of early work with the shallowness which a reasonable economy generally necessitates. As the style developed the architects gradually learned how to produce fine effects with more moderate means. Their work became more scientific, and a skilful adjustment of thrusts and counterpoises enabled them to produce effects of wonderful elegance and beauty, showing great engineering knowledge and clever economy of materials. I must say it is rather affectation to close our eyes to the real progress thus made, the more so as the conditions under which the later architects worked are so very much more parallel to those of our own day than were those of their predecessors.

In the smaller churches, especially, we see in the more developed style a wonderful advance in the power of producing fine effects with small means. The great development of the clerestory shows a thorough grasp of the true principles of internal effect. Take an ordinary early church with lean-to aisles of no great height, and a high-pitched nave roof springing from directly above the side arcades. The result of this arrangement is that the light which is admitted almost entirely from the aisle windows enters at a comparatively low level, much below that of the roofs, and strikes upwards, a distribution quite inconsistent with a dignified internal effect. Such an interior, however large its scale, and however great its beauties of detail, must always have a somewhat unimpressive and homely character. The later architects, with a true perception and a real grasp of the matter, felt this very clearly, and what did they do? They carried up the nave walls as high, perhaps, as the ridge of the early roof, pierced them with windows to the utmost possible extent, and placed upon them a roof either flat, or of a very moderate pitch. The new windows they filled with glass of a beautiful silvery tone, treated with great breadth of effect in point of colour, and with a very large proportion of white. The principle of lighting is now reversed. A vast body of softly toned white admitted from above gives an

effect at once of dignity and of space, and with no very great addition to the cubical contents of the building, the whole tone is raised from one of mere simple homeliness to a character that is impressive and even stately. Indeed a flat roof, which it is the fashion to decry, has internally one of the great advantages which groined vaulting possesses, in that it enables the windows to run up to a level very little below that of the highest part of the interior, so that the whole building is lighted from above—a point of the highest importance in internal design.

In looking at an old church as it now stands we are too apt to think of it as made up of portions of different dates incongruously put together, and as owing that beauty of effect as a whole, which beyond all question it possesses, to chance and happy accident. We forget that in the vast majority of instances it was the later architects who deliberately impressed upon the building the character which now especially distinguishes it, that the church as it stands owes to them its general outline and proportion, and that unity of effect which makes it, in spite of all its varieties of style, a complete and satisfactory whole. The changes they made were done deliberately with the object of producing that result which, in spite of all our theories, we instinctively admire, and the fact that the earlier work which they retained, so far from producing incongruity, concords so well with all the rest only shows how thoroughly the later artists understood their work, how well they had mastered the problem of reconciling new with old, and multiplicity with unity, and of subordinating the variety of the parts to the harmony of the whole. Whatever style we may think well to adopt, these lessons ought not to be neglected.

There are, indeed, many early examples in which the same principles have been grasped. We often find, even in country churches of Decorated date, finely-developed clerestories, and it is by no means necessary to adopt a later style in order to profit by the experience of the later architects. Let us aim not at a mere antiquarian reproduction of any one period, but at a rational use of the best qualities of each. We shall then have art instead of dilettanteism, and architecture in place of archaeology.

#### STATELY SYDNEY.

A CORRESPONDENT of the *Scotsman*, writing from Sydney, N.S.W., on March 4, says:—

Stately Sydney sits enthroned on swelling hills by the margin of her lovely harbour. She extends her beautiful arms over every promontory and island in the sea before her. She is not a city of palaces, but she is a city of stately buildings. Looked at from the sea, she seems to rise up in clear perspective into the far distance. Red roofs alternate with the darker slate, and white buildings are scattered in all directions. When you enter her streets you find massive stone erections of all orders of architecture, but all in good taste. She has provided herself with splendid Government buildings, though they are not capable of accommodating all the departments of the administration. Some of these departments are housed in buildings scarcely less fine than the Government buildings themselves. Thus the Lands Department has a magnificent house of its own, while smaller divisions of the Government are housed in smaller houses grouped about the main buildings. From the windows of the Government buildings a magnificent panorama presents itself. Government House, which is the lodging of the Governor for the time being, is a fine picturesque building embosomed in trees on a point extending out into the harbour. The grounds adjoin the Botanic Gardens—perhaps the finest gardens of the kind I have ever seen. The Domain, so-called, extends in broad acres from the gardens still more to the right. All this can be seen from the windows of the Government buildings. Of course, there are glimpses of the harbour at every turn. Its blue waters seem to intrude themselves into the green leafage of the land. Not far away North Sydney is to be seen, and further away you catch glimpses of Manly and other suburbs of the great city itself. Everywhere there is evidence of the care and forethought of those who have had the planning of the city and of those who have its custody. Its municipal building might be taken as a model for a similar building in Edinburgh. It would not in any way disgrace your classic city, while it would afford to the municipal authorities ample room for the performance of their arduous duties. One of the features of this municipal building is a fine hall, into which as many as 6,000 persons have been gathered. A splendid organ is placed in it, said to be the largest in the world. In fulness of tone, in softness, in delicacy, in all that goes to make one of the noblest of musical instruments, it can scarcely be rivalled.

Close by the municipal buildings there has arisen a huge edifice in which the beautiful and the ugly are combined in the strangest fashion. It is intended for public markets. It might be a palace for a king. It would be difficult to say what is the precise order of architecture adopted, but the effect is excellent until you get to the roof. Upon this huge copper or brass

cupolas, something of a Moorish character, have been erected, and they seem to give an incongruous character to the whole edifice. The Post Office, again, is an extremely fine building standing well out, and affording ready access to all the departments of the business that has to be performed. One feature, interesting to a certain extent in connection with the buildings in Sydney, is the number of fine edifices that have been erected by the Roman Catholics. They are to be seen in all directions. Cardinal Moran lives himself at Manly in a huge building which is at once a palace and an educational institution. A great cathedral is rising in the centre of the city. Churches are found in all directions. Educational colleges are studded here and there—one of them forms an outlying adjunct of the University. Not only have public bodies erected fine houses for themselves and their businesses; commercial men have followed in their wake or have led the way. In every direction you find great warehouses, all built with regard to picturesqueness, and of more or less architectural excellence. The general effect is to give to Sydney a stateliness which can be equalled by few cities in the world.

But the chief glory of Sydney is the number and extent of its open places. In every public garden statues are found. They are replicas of more or less well-known pieces. They, again, afford ample evidence of the excellence of the climate and the absence of that dreary smoke which disfigures statues in London and Edinburgh and in every town in the United Kingdom. Being made of plaster, the expectation might be that they would become grimy and perhaps grotesque in their out-of-door appearance. They are nothing of the kind. They are perfectly white and clean, and look for the most part as if they had just come out of the sculptor's studio. The Governors of Sydney have thus had regard not only for the health and welfare of the people in providing great public open spaces; they have done something and not a little to cultivate the taste of the people by the artistic adornment of these places.

In furtherance of this part of their work they have erected in the Domain a spacious art gallery. It has in it many pictures of great and well-known excellence. It is admirably arranged and there is space in it for far more objects of art than it yet contains. In the course of a comparatively short time it need not be doubted the munificence of Sydney citizens and the Government will add to its art treasures and make it one of the finest galleries in the southern hemisphere. At present it is enriched by loan collections from South Australia and Victoria and other parts of Australasia.

It would be a misuse of language to say that the Houses of Parliament at Sydney are fine buildings. They were erected many years ago when money was not plentiful and wood was. Thus they are still of wood, and they seem to be altogether out of harmony with their surroundings. They face one of the finest streets in the world except Princes Street—Macquarie Street. There is talk of a proposal to erect new Houses of Parliament, and there need be no difficulty in crediting the rumour, for the public spirit of New South Wales men could not be content that their legislators should be housed in so comparatively insignificant a building as the one now at their command. It may be that the erection of a new building will be delayed or the plans in connection with it altered because of federation, which seems to be coming to the Australian colonies. Be that as it may, it is certain that the people of New South Wales will not be content to go on with wooden Parliament Houses having no pretensions to architectural excellence.

## THE COMPLETION OF SOUTH KENSINGTON MUSEUM.

THE following memorial has been addressed to Sir John Gorst on the subject of the South Kensington Museum:—To the Right Hon. Sir John Gorst, Q.C., M.P., Vice-President of the Committee of Council on Education.

We, the undersigned, practising various branches of the arts as a profession, seeing that a committee of the House of Commons, of which you are chairman, has been appointed to report on the South Kensington Museum, venture to address this memorial to you, trusting that you will bring it before that committee, and also that, as the Minister responsible in the House of Commons for the Museum, you will use your influence to give effect to our prayer.

The South Kensington Museum was founded in order that "all classes might be induced to investigate those common principles of taste which may be traced in the works of excellence of all ages." The extent to which it has stimulated an interest and educated opinion in art matters in this country, and the profound impression it has made on the progress and revival of what may be termed the industrial arts, is well known and acknowledged by all those in a position to judge, not only in this country, but on the Continent and America, where the South Kensington Museum has been avowedly taken as a pattern on which to found various national museums.

The extraordinarily valuable collections, which have been enriched by gifts and bequests valued many years ago at more than 1,000,000/., cannot, however, be properly arranged or seen, much less studied, owing to want of space; while the external appearance of the museum is a discredit to the nation.

We, your memorialists, therefore earnestly pray that active steps may be taken by Parliament to complete the building; and we share the opinion already expressed that no more fitting national memorial of the 60th anniversary of the accession to the throne of Her Most Gracious Majesty could be made than the completion of a museum which owed its existence to her Royal Consort, and which Her Majesty has declared that she has taken under "her special and personal protection."

Edward J. Poynter, H. H. Armstead, Edward Burne-Jones, Walter Crane, Kate Perugini, C. E. Perugini, W. Holman Hunt, W. B. Richmond, Laura T. Alma-Tadema, L. Alma-Tadema, Frank Dicksee, James C. Hook, Hamo Thornycroft, Henry T. Wells, Val C. Prinsep, John S. Sargent, David Murray, Hubert Herkomer, Briton Rivière, Luke Fildes, George J. Frampton, Geo. H. Boughton, Arthur Hacker, Ernest A. Waterlow, B. W. Leader, Jas. Sant, J. W. Waterhouse, John L. Pearson, J. McWhirter, Andrew L. Gow, John Brett, Peter Graham, Henry Woods, George Aitchison, W. L. Wyllie, E. Onslow Ford, Thomas G. Jackson, Stanhope A. Forbes, Alfred Parsons, H. S. Marks, Marcus Stone, Thomas Brock, Seymour Lucas, Edwin A. Abbey, Colin Hunter, J. W. North, Edward J. Gregory, G. D. Leslie, Alfred East, C. E. Hallé, Arthur Lucas, Edgar Barclay, G. P. Jacob Hood, Moffat Lindner, Robt. W. Allan, C. Napier Hemy, Arthur Melville, Henry S. Tuke, W. Graham Robertson, Feodora Gleichen, Philip Burne-Jones, Edwin A. Ward, G. F. Watts, John Parker, J. L. Pickering, Thorne Waite, J. Coutts Michie, Annie L. Swynnerton, Elinor Hallé, Frank Dillon, Herbert A. Olivier, Charles W. Wyllie, Philip Norman, Edward Stott.

A memorial to the same effect was addressed by the same signatories to the Duke of Devonshire. This contained an additional suggestion, namely, that the completed buildings should be "hereafter named the Victorian Museum."

## PYRAMIDS AND THEIR RELATION TO MONUMENTAL AND SACRED ARCHITECTURE.\*

MY first subject will be the pyramids of Egypt, second the pyramids or teocalli of Mexico and Central America, and last the pyramidal shaped temples of India.

There is no doubt as to the intended use of the pyramids of Egypt. They were strictly monumental, and were erected as a place of deposit for the remains of the person for whom they were built. The theories that they were astronomical monuments, or large storehouses, or memorials of a system of weights and measures intended to be universal, as claimed by some writers on the subject, are not supported by the accounts of the ancients or by the Egyptian inscriptions and other testimony.

The fact that the pyramids are found in the midst of a necropolis, that they contain sarcophagi and mummies, and that the inscriptions on the tombs of many priests mention as a special honour that the deceased officiated at the funeral services held at the pyramids, seem to prove that they are tombs and nothing else. As the Egyptian tombs have always borne one and the same character, and only the manner in which they were adorned varied with the tastes of the period, their epoch may be determined with great certainty.

For the first eleven dynasties, or previous to 3,000 years before Christ, the tombs were in the form of a "mastaba," or merely rectangular walls looking like unfinished pyramids, and their interiors were richly decorated with sculptures and paintings referring either to the life of the deceased or to the gods of the current religious system. During the middle empire and until about 1,600 years before Christ, the "mastaba" were superseded by small pyramids and by passages cut in the rocks, and the divinities were seldom represented upon them. In the next period, or until about 340 years before Christ, excavated tombs prevailed and statuary and images of the deceased were superseded by those of a mythological character. The pyramids are only enlarged "mastaba" and as such belong to the first period.

An hour's ride from Cairo carries us back through the vistas of history to the earliest monuments of civilised man. We have the mosque of the 'Ams, the oldest building of Cairo, which has yet seen only twelve centuries pass since its foundations were laid, and we stand before the pyramids of Gizeh which have looked down on the whole course of man's development from ages when Phœnician and Greek had not even a name, when

\* A paper by Mr. Cyrus K. Porter in *Stone*.

the oldest of all the Troys was still in the dim and distant future. At a time when our Aryan forefathers were pasturing the flocks and herds on the steppes of Asia, and when a tent or a reed hut was the highest achievement of architecture everywhere else, in the Nile valley the Egyptians were building those stupendous monuments which are still the wonder of the engineer, and were painting those frescoes and modelling those statues which represent a stage of civilisation to which the Greeks did not attain until thirty centuries later, and which half of the world has not reached even now.

The three great pyramids of Gizeh are the most remarkable and the best known of all those of Egypt. Of these, the first erected by Cheops or Suphis, as he is sometimes called, is the largest. The next by Chepheren, his successor, is scarcely inferior in dimensions; while the third, that of Mycerinus, is much smaller, but excels the two others in this, that it has a coating of beautiful red granite from Syene, while the other two were cased only with the beautiful limestone of the country. The dimensions of these three as ascertained by the copings are as follows:—

Cheops—Side of base, 760 feet; height, 484 feet.

Chepheren—Side of base, 707 feet; height, 454 feet.

Mycerinus—Side of base, 354 feet; height, 218 feet.

Each one was commenced over a sepulchral chamber excavated in the rock, and during the life of the ruler for whom it was intended the work of building up over this chamber went on, a very narrow passage way being kept open as the courses of stone were added by which access from the outside was secured to the central chamber. At the death of the monarch the work ceased, and the last layers were then finished off and the passage way closed up. The foundations for the structure were excavated in the solid rock, sometimes to the depth of 10 feet, and upon this the great stones were arranged and built up layer upon layer, and one shell succeeding another, and the spaces being filled in with small stones loosely packed. The piles were constructed of blocks of red or Syenitic granite from the quarries of Asswan, and also of others of a hard calcareous stone from the quarries of Mokattam and Turah. They were of extraordinary dimensions, their thickness varying from 2 feet to more than 4 feet, and when arranged one upon another, forming steps up the outer slope, the thickness of the stones determined the height of the steps. Those near the top are of thicker stones, but the blocks are of moderate length compared with those at the base. To quarry and remove the immense blocks of stone to the pyramids and then raise them to their respective places required no little engineering skill, notwithstanding an unlimited amount of human labour was at command. Near the summit the number of men that could aid in raising the huge stones must have been comparatively small for the want of room, and it seems that some mechanical power must have been employed, besides any which we know they possessed. The probability of this is confirmed by the fact that cavities have been found in the stones, which appear as though they might have been worn by the foot of derricks turning in them.

The three pyramids of the Memphis group stand on a plateau about 137 feet above the highest rise of the Nile, not far apart and about on a north-east and south-west line. Like the other pyramids of Egypt, the four sides are directed towards the cardinal points of the compass. The largest pyramid, that of Cheops, covers at present an area of between 12 and 13 acres. The dimensions have been reduced by the removal of the outer portions to furnish stone for the city of Cairo. Thus despoiled, the walls have lost their smooth even surface in which state they were left by their builders, who filled in with small stones the angles formed by the recesses of each upper layer and cut away the projecting corners of the great blocks, thus leaving an even surface on each side sloping to an angle of 51 deg. 50 min. By stripping off the outer casing the courses of stone appear in the form of steps, which though ragged and unequal can be ascended even by ladies. The Great Pyramid has 203 of these steps, the lower ones being 4 feet 10 inches in height. The horizontal surfaces were nicely finished and the stones were joined together with a cement of lime without sand.

The masonry of the Great Pyramid consisted originally of over 89,000,000 cubic feet, and its total weight is estimated at 6,316,000 tons. Its only entrance is on its north face about 24 feet east of its central line, and 49 feet above its base line. The masonry about it is much broken away, and the piles of broken stone reach from the ground nearly to its level. This passageway is only 3 feet 11 inches high, and 3 feet 5 inches wide. It leads down a slope of 26 deg. 41 min., a distance of 320 feet 10 inches to the original sepulchral chamber, commonly known as the subterranean department, and beyond this 52 feet 9 inches into the rock. This passage is 2 feet 7 inches wide and 2 feet 8 inches high. It is supposed that it was intended to excavate another chamber at the end of this passage, and that it was not done on account of the monarch continuing to live until it was found expedient to close up the mouth of the passage with the external casing of masonry.

The sepulchral chamber is 46 feet long, 27 feet wide and 11½ feet high. At 63 feet from the entrance a branch passage connects, which rises at an angle of 26 deg. 18 min., and thus extends a distance of 124 feet, where it becomes level and extends 109 feet further. This connects with several chambers and passages. One situated nearly in the centre of the pyramid and 67 feet above its base is known as the Queen's Chamber. It is 17 feet by 18 feet 9 inches, and 20 feet 3 inches high, and has a groined ceiling. It appears to have been intended for a sarcophagus, but when discovered was found empty, the only sarcophagus found being in what is called the grand or King's Chamber. This apartment is 34 feet 3 inches long, 17 feet 1 inch wide and 19 feet 1 inch in height. It is lined with red granite, highly polished, single stones reaching from floor to ceiling. The ceiling is formed of nine large slabs of polished granite reaching from wall to wall. Above the ceiling are five small chambers built apparently to protect the ceiling of the chamber from the immense weight above it. The room is perfectly plain and contains only a sarcophagus of red granite 7½ feet long, 3 feet 3 inches wide and 3 feet 5 inches high, which is too large to have been introduced through the passageway, and must therefore have been placed in the room when this was built. It contained a wooden coffin and the mummy of the king, which disappeared when the pyramid was first opened and plundered. In the construction of the pyramid arrangements were made for blocking up the important passages with huge masses of granite, and the obstacles thus interposed have greatly impeded their exploration, and sometimes rendered it necessary to open new passages around the obstructions. It is not improbable that the ancient Egyptians themselves violated the tomb of Cheops, or that Cambyzes, the king of Persia, entered it. Arab historians record that the caliph Momman, in the beginning of the ninth century, forced his way into the pyramid in order to rob it of its supposed treasures. He found nothing but empty chambers and a stone sarcophagus containing a wooden coffin which held a richly-decorated mummy.

The second pyramid stands on a base 33 feet above that of the Great Pyramid and in an excavation made for it in the rock. It has an angle of 52 deg. 20 min. The upper portion of its casing is still preserved. It has two entrances, one 37 feet 8 inches above the base, the other built out in front of the base, each leading by an inclined passage about 100 feet long to the same sepulchral chamber. This chamber is 46 feet 2 inches long, 16 feet 2 inches wide and 19 feet 3 inches high, and has a roof the shape of the pyramid. It contains a granite sarcophagus 8 feet 7 inches long, 3 feet 6 inches wide and 3 feet high. This pyramid was entered by Belzoni in 1818, who found a cufic inscription recording the visit of a caliph and the opening by him of the pyramid A.D. 1196. The only remains met with were those of a bull, the Egyptian god Apis.

The third pyramid, as before remarked, is much smaller than the others. It was explored in 1837 by Colonel Vyse, who discovered several apartments in one of which was a highly-finished sarcophagus, a mummy case bearing the name of King Menkara and the body of a workman. The last two are now in the British Museum, but the sarcophagus was lost on the passage. This pyramid, though the smallest, is the best constructed of the three, the style of the work being more costly than any of the other pyramids of Egypt. In the same vicinity are six smaller pyramids supposed to be the tombs of some of the relatives of the kings who built the larger ones. A pyramid is simply a cairn or burrow, only its stones are laid regularly and their edges are carefully finished instead of being roughly thrown together. The principle of the pyramid is almost always the same. A rocky eminence on a deserted tract of land lying between the Nile and the Libyan hills, and above the reach of the annual inundation, was excavated for the reception of the king's sarcophagus, and a sloping passage was cut to connect the royal sepulchre with the surface. Above the sepulchre, both to protect it from the inroads of the sand and to mark the spot, a large block of stones was erected, almost in the shape of a cube, but slightly tapering or battering towards the top. This was done early in the king's reign, and if he died at this point his mummy was inserted in the tomb, a small pyramidal cap was placed on top of the block and triangular pieces were added to the sides, and a small pyramid effectually closing the royal sepulchre was then complete. If the king, however, continued to reign, he deferred the cap and sides and instead of them put other blocks around the base, so as to form a second stage upon which he erected another casing to his cube, thus increasing its size. The longer the king lived the larger became his pyramid, so that it is possible to roughly estimate the duration of his reign by the height of his pyramid. It is quite impossible for me to give a minute description of individual pyramids within the scope of this paper. Volumes might be and have been written on this interesting subject and yet it is not exhausted. In this connection I will only refer to one other pyramid—one of the number included in the group of eleven in the second great cemetery of Memphis, the necropolis of Sakkorah. It is known as the pyramid of

steps. This pyramid is supposed by some writers to have been built by Uenephes, of the first dynasty. If so it is the oldest monument in the world. It was constructed of an inferior quality of limestone, quarried probably in the neighbourhood. Its six steps with the angles not filled up reveal the principle of pyramid building. It has the peculiarity of an oblong instead of a square base, and unlike the other pyramids it is not set square with the cardinal points of the compass.

Pyramids as monuments to the illustrious dead were not confined to Egypt. Ethiopia contributes three groups of monuments in the form of pyramids. The principal group is at a place called Dunkelah, in latitude 17 degrees north, which is supposed to be the site of the ancient city of Meroe. Another is at Gibel Borkal, and a third is at Nourri, a few miles down the river from Gibel Borkal. Compared with the great Egyptian pyramids these are most insignificant in size. The largest ones in each of the three groups are as follows:—That at Nourri is 110 feet by 100 feet at the base, that at Gibel Borkal is 88 feet square, while at Meroe none exceed 60 feet each way. They also differ in form from those in Egypt, being much steeper, as their height is generally equal to their base. They also possess a roll moulding on their angles and each has a little porch or pronaos attached to one side generally ornamented with sculpture, and forming either a chapel or more probably a place where the coffin of the deceased was placed. We learn from a celebrated Greek traveller and historian that so far from concealing the bodies of their dead, the Ethiopians had a manner of preserving them in some transparent substance which rendered them permanently visible after death.

I will close this part of my subject with the following extract from the writings of a learned and enthusiastic writer on Egyptian history. Mr. Stanley Lane Poole, in his valuable contribution to "Picturesque Palestine," says:—

The people who built the pyramids 4,000 years before Christ were no barbarians, no nomad tribes of lacustrine peddlers. They were people with a profound philosophy, a lofty religion, a remarkable and individual art, a refined and complex society. If the progress of man from savagery to civilisation marched then by the same slow labouring steps as in later times, the Egyptians must have been a nation for thousands of years before they could have built Memphis with its chain of grand sepulchres. It is like standing on the borders of infinitude when we think of this wonderful antiquity.

The immeasurable ages of geology and the weird traces of primitive man give one an overwhelming sense of insignificance, but these tell us only of a barbaric savage existence with scarcely the beginnings of a higher life.

The monuments of Egypt show us man living as civilised a life as ever Roman conceived. As civilised in some of the best senses as any life we lead now, and there they stop short and meet us like a closed door, bearing on its threshold the footprints of myriads of inhabitants, but suffering no man to enter and see them. It is not the age of the pyramids that awes one most, but the thought of the unknown past that preceded their mighty birthday. Five thousand years ago they stood where they stand now, but the men who looked upon them belonged to another immeasurable antiquity when pyramids were not, of which we see the end but not the process, and whereof there remains no record but the result.

In the brisk hustling bazaars where the traders and dealers meet to exchange goods, the brown Nile labourer may be seen bringing his produce. In appearance he is much the same being that he was when the pyramids were being built, but now he can neither build nor paint nor write. Turn into the museum close by and you will see the statues and pictures and writing on the walls, extorted from the grasp of the desert sand which people with the blood of modern Egyptians in them produced in lavish quantities and amazing perfection. A modern "fellah"—one of this very people's descendants—is looking at the works of his forefathers in stupid wonder. He does not understand them. He knows that he and his countrymen can do nothing like them now. How they ever came to do them and what took away the power of such works from them are some of the questions that crowd upon the mind as we contemplate the stupendous works. Surely "Time mocks all things, but the pyramids laugh at time."

(To be concluded.)

## TESSERÆ.

### Church Spires in Landscapes.

NO object has, perhaps, been more frequently praised and censured in its turn than the Gothic spire. In reconciling these extremes it must be observed that this object, when viewed from within an ancient town or city or near the suburbs, where it groups with the gables of antiquated mansions, with their varied and ornamented wooden pinnacles, over which they rise, partially obscured in smoke and misty grandeur, relieved and backed by sober, neutral and greyish clouds, their importance is principally evident; they are enlarged by the imagination, and act as a crown and finish to the whole, but please less if the upper lines of the towers on which they stand

are not visible, and in this case they gain more by being seen geometrically than perspectively, as great objects, like the heroes of the drama, approach the audience with unbending solemnity and measured step, while the playful variety of action is thrown on the minor characters. The spire also, seen as one grand object, rising over its rich western front, ornamented with pinnacles and smaller spires; the tower on which it stands, seen at its upper parts; these, then, make one consistent mass, and do less mischief to the grandeur and solemnity of the whole than thus seen behind the broader masses of the buildings; but when seen as an object in a landscape the spire should be humble and diminutive, bending in with age, and belonging to a village, its form best corresponding with the objects beside simple and quiet river scenes, such as frequently occur in pictures of the Flemish masters, accompanied with rustic cottages, pollard willows, elder trees and bending rushes; the yellowish or warmish green parts of distant meadows, relieved with lightish cattle, or figures in white shirts or frocks, and the skies principally composed of clouds such as may belong to fine weather, this choice being prevalent in fine works composed of neutral tint and a little purple, remarking that as neutral tint is no colour grey must be composed of neutral and a little blue, and to make a pearly grey a little lake must be added; this will serve for a shade to the darker parts of the sky, which may be more neutral if in great masses. Small spires, adapted to these kind of subjects, may help to form the most agreeable pictures belonging to the pastoral class; but if there be one object more than another repugnant to the eye of taste, it is the view of a lofty spire seen from fields and other places moderately distant from town, for as the awfulness and sublimity of attitude is admitted to owe much to lines which rise directly up towards the skies, the spire not only destroys, by comparison, the magnitude of all the trees and other objects with which it cannot harmonise, but instead of supporting the equal dignity of a tower, which only terminates its career while soaring, appears with its buttresses like a slender giant, who has outgrown his strength, and is propped up with a fool's cap on his head.

### Representation of Trees.

The great difficulty attending the representation of trees consists in the necessity there is for the application of general knowledge and rules of art, which must be added to great practice and a feeling for the beauties of form. Even industry and ability must be a long time exerted before anything like freedom and a general character of execution can be obtained, provided the student has only to rely on his own observation of nature, and has no access to the masterly performances of established artists, which may save him many years of labour, for by referring only to nature in the first instance the painter will be rather apt to imitate the infancy than the maturity of art, as it is not the number of leaves that give quantity, but variety in their sizes, tones, distances, depths and colours, for as there is more information to be gained by viewing six coins of various sizes and reigns than a thousand coins of the same date and impression, so will a small variety of weeds and leaves appear more numerous than a great quantity of the same kind. The neglect of this principle is one of the reasons why those trees which are so much laboured give offence rather than pleasure to an experienced eye; and it appears to have been in many instances the fault of Zuccarelli, who, though he executed his objects with masterly touches, yet was too apt to make the leaves of his trees equal in size on every side of them, which fault is perpetuated in many engravings from his works; and this always causes a tree, however well executed in form, to appear artificial. But if between two branches firmly executed in colours a third branch is seen of a greyish and paler green, with the leaves smaller and less definite in their forms, it will not only give the appearance of a great quantity of leaves, but will help in some measure to harmonise the tree with the blue of the sky, or with grey clouds behind the trees, which likewise help to prevent the foliage from appearing harsh. To acquire a freedom and facility of execution, it is requisite the learner should often, on a small scale, copy the regular and even formal representation of clusters of leaves, and such as small branches of ash or a rose-bush would afford, and should acquire the power of making neat oval leaves with one or two touches of a full sable hair pencil; and when he can do these quickly he may then relax from the regular forms of leaves, and by attending principally to the masses execute the leaves with the looseness of character observable at a small distance in nature.

### Orientation of Temples.

Nothing could bring out more clearly the full significance of the west as the region of death than the details of the consecration of the pickaxe by the murderous Thugs of India, worshippers of Kali, the death-goddess. In her honour it is that the victims are murdered; to her is dedicated the pickaxe with which the graves of the slain are dug. On that dreadful implement no shadow of any living thing must fall; its consecrator sits facing the west to perform the fourfold

washing and the sevenfold passing through the fire, and then, duly consecrated, it is placed on the ground, and the bystanders worship it with faces turned to the west. On the other hand, the thought of the deities as in the region of sunrise is familiar to the savage mind in South America, as when the Jumanas turn the faces of their dead to the east, where dwell the two great deities, the Good and Bad Spirit; and so the Guarayos turn their corpses to the east, to go to the happy country of Tamoi, the grandfather, the ancient of heaven. In countries where sun-worship prevails, there prevails with it the right of adjusting the temple and turning the worshippers to the east. One of the great ceremonial rites of the Apalaches was performed at sunrise, when the priest stood at the door of the temple hut and adored the eastern sun; the cave-temples of the Floridans opened eastward to receive the first rays of the luminary; in Mexico men turned to the east in prayer, and the kindred Nicaraguans declared the gods to be in the region of sunrise; in Peruvian sun-temples the doors looked east, so that at dawn the sun's rays fell on the golden disc, and the people saw and greeted their national deity. This is the rite which the prophet Ezekiel describes as he sees it in horror-stricken vision:—"At the door of the temple of the Lord about five-and-twenty men, with their backs toward the temple of the Lord and their faces toward the east, and they worshipped the sun towards the east." Predominant as sun-worship was in Aryan thought, what is more natural than that the Brahman should turn to the east, and that Vitruvius should give directions so elaborate for adjusting the temples and altars of the immortal gods by the same rule of east and west followed by church builders now? In speaking of the solar symbolism of east and west within Christianity, such exceptional cases are excluded as that Christian sect described by Leo I. in the fifth century as stopping on a hill and bowing to the rising sun before entering the basilica of St. Peter, which the Pope says "comes partly from ignorance and partly from the spirit of paganism, and afflicts us extremely." But such ceremonies as the baptismal rite about the fourth century, which contrasts east and west with the utmost fulness of symbolism cannot be passed over. Cyril of Jerusalem thus describes the scene:—"Ye were first brought into the anteroom of the baptistery, and placed standing toward the west (the sunset), and then commanded to renounce Satan by stretching out your hands against him as if he were present. . . . And why did ye stand toward the west? it was needful, for the sunset is the type of darkness, and he is darkness, and has his strength in darkness; therefore symbolically looking to the west ye renounce that dark and gloomy ruler." Then turning round, to the east the catechumen took up his allegiance to his master, Christ. Thus Jerome says:—"In the mysteries we first renounce him who is in the west, and dies to us with our sins, and so turning to the east we make a compact with the Sun of Righteousness, and promise to be his servants." This perfect double rite of east and west is retained in the Eastern Church, and may be seen in Russia to this day. The partial ceremony of orientation of churches and the practice of turning toward the east in worship, which quite naturally caused early Christians to be accused of being sun-worshippers, are common to both churches.

### The Westminster Chapter-house.

From the actual building accounts which have been preserved, it is evident that the chapter-house was erected in A.D. 1250-53, so that it formed part and parcel of the original plan of the church, though a separate structure. It stands over a crypt, which may or may not have belonged to a previous building devoted to similar purposes. It is approached from the outer cloister by an outer and inner vestibule, the former being of limited height, owing to its passing under the dormitory, the latter lofty, and containing the flight of steps by which the raised level of the chapter-house is reached. The outer vestibule is divided into two walks or aisles by small columns of Purbeck marble, and the arch in the cloister by which it is entered is exquisitely carved. The inner vestibule is divided into two unequal bays, pierced on both sides with windows; those on the northern side, however, look not into the open air, but towards the altar of St. Faith in the revestry. The building is an octagon, the diagonals of which measure 60 feet, and it is loftier than most other buildings of the same kind. The central pillar is of Purbeck marble, consisting of a column surrounded by eight detached shafts; it is lofty and light, and the groining which springs from it has been restored according to the original design. Seven bays of the edifice are each occupied by a spacious window, which nearly fills the whole width between the corner shafts. The spaces between the windows are arcaded with five arches in each of a trefoil form and richly moulded. The five arches against the eastern wall are much richer and more deeply set than the others. They probably formed the seats of the five greater dignitaries of the abbey, namely, the abbot in the centre, the prior and out-prior and the third and fourth priors. The seats all round are of stone, and on the backs of these was a series of paintings. The chapter-house,

as is well known, was the place where the monks and other dignitaries of monastic buildings met to transact the general business of their order, but that at Westminster has its political as well as its religious associations. Here, by the consent of the then abbot, in 1377 the Commons of England first held their meetings, as part of the King's Parliament, and here they continued to hold their meetings until 1547, when Edward VI. granted them instead the use of St. Stephen's Chapel.

### Royal Academy Exhibition.

SIR,—Owing to a clerical error, Mr. Arthur R. G. Fenning's name was omitted from the catalogue of architectural illustrations now in the Academy, as being joint architect with me of the design for the new Presbyterian College at Cambridge. In justice to him, I shall therefore feel greatly obliged if you can find space to insert this letter in your next issue.—Yours obediently,

W. HOWARD SETH-SMITH.

46 Lincoln's Inn Fields, London, W.C.:

May 11, 1897.

### GENERAL.

**Mr. F. J. Warden-Stevens, A.M.I.E.E.**, of 34 Victoria Street, Westminster, has, we understand, been appointed the consulting engineer to the Poplar Guardians, to advise in the electric lighting of the important workhouse buildings and offices and also to report on the present boilers and engines.

**The Private View** of the Society of Miniature Painters, second exhibition, will take place on Saturday, 15th inst., at Messrs. Graves & Co.'s gallery, 6 Pall Mall, S.W., and the exhibition will be open to the public from the 17th inst. to the end of June. All exhibits will consist of works by contemporary artists.

**The Twenty-first Ordinary Meeting** of the Society of Arts will be held on Wednesday, May 19, at 8 P.M., when a paper on the "London Water Supply" will be read by Prof. Percy F. Frankland, Ph.D., F.R.S. Sir Douglas Galton, K.C.B., F.R.S., will preside.

**Mr. Sydney A. Smith**, the winner of the Penfold medal for obtaining the highest number of marks, and of the Driver prize for conspicuous merit, in the professional Associate examinations of the Surveyors' Institution, is twenty-one years of age, and is possibly the youngest among the non-student candidates. He commenced professional life in the office of Messrs. Ernest George & Yeates, of Maddox Street, and is now with Messrs. Weatherall & Green, of 22 Chancery Lane. He served his articles to Mr. C. R. Thornton, of Westminster.

**The Oxford Municipal Buildings** were opened on Wednesday by the Prince of Wales. The building, which was designed by Mr. H. T. Hare, includes municipal offices, town hall, council chamber, mayor's parlour, assembly-room, public library, sessions court, and quarters for the police.

**The Obelisk** in Ludgate Circus is to be moved from its present position in order that it may more nearly coincide with the altered line of footway in Fleet Street, which is due to the recent widening.

**The New Exhibition** of the Grafton Gallery is devoted to theatrical portraits and other memorials, and was opened on Thursday.

**The New Public Halls** which have been erected in Selkirk at a cost of about 7,200*l.*, and which are to be known as the Victoria Halls, in commemoration of the Queen's Jubilee, were opened with much pomp and circumstance on the 6th inst. The buildings contain a large central hall fitted with a recessed gallery, a smaller hall and caretaker's house, a complete suite of retiring-rooms and other accessories, and several committee-rooms. The internal arrangements of the building are simple and excellent, and the principal elevations are characterised by chasteness and effectiveness of design. The architect was Mr. Hippolyte J. Blanc, A.R.S.A., Edinburgh.

**The Public Free Library** and news-room which has been erected by the free libraries committee of the Moss Side District Council was opened on Saturday afternoon by the Marquis of Lorne, M.P. The building has been erected from designs prepared by Mr. Acton, the surveyor to the District Council, the cost being about 3,000*l.* It includes a large public room which may be used for meetings, concerts, &c., a library and news-room, and, in the basement, classrooms in which some of the technical instruction classes held under the District Council may be carried on.

# The Architect.

## THE WEEK.

ON Tuesday next the Engineering Conference will be opened at the Institution of Civil Engineers, when the President, Mr. J. WOLFE BARRY, will deliver a short address. There will be six sectional meetings. In the railway section the subject of permanent way will be discussed, Mr. WEBB, of Crewe, being the first speaker. In the harbour section a paper on "Concrete in Marine Works" will be read. The transmission of power by electricity, water and other means will be the principal subject in the electrical section, and among the speakers will be Mr. PREECE, Dr. HOPKINSON and Mr. ELLINGTON. Water in shafts will come under consideration in the mining section, and experiments on models of merchant ships in the naval section. During the afternoon there will be visits to the Central Subway and other works. On Wednesday some members will visit Dover Harbour and others the Blackwall Tunnel and Woolwich Arsenal. Sanitation will be prominent at the meetings, for papers will be read on waterworks, sewerage, gasworks, refuse destructors, bacteriology, &c. On Thursday all sections will be busy, and the experiment is likely to be successful in revealing the latest advances in the most important branches of engineering.

ALL who can appreciate French acting of varied classes should not neglect the performances which are being given by Mdlle. JANE MAY at the Royalty Theatre. That lady holds a position of her own in Paris, and the general verdict which assigned it to her has been endorsed in London. Her command of her art is so sure, it is difficult to say whether she is more attractive in speaking or in mimetic parts. In both she can sway her audiences. Yesterday afternoon Mdlle. JANE MAY appeared in "Le Monde où l'on s'ennuie." It is an advantage to have the performances in the afternoon, and they merit the support of all who love refined acting.

IN his report which was issued this week Sir ARCHIBALD GEIKIE, the director-general of the Geological Survey, records that Mr. JAMES BENNIE has brought to light traces of two Arctic tarns that once lay among the sand-mounds over which the northern part of the city of Edinburgh has been built. The deposits which they have left behind them have been trenched in making a sewer several hundred yards long to complete the Water of Leith purification scheme between Pilrig Street and Broughton Street. The chief feature of each lake-site was the occurrence of a bed of lake-peat composed of peaty mud and layers of compressed mosses and other vegetable *débris*, but with no clay or sand intermixed. These deposits lay immediately under the vegetable soil. In both lake bottoms a fine-grained silt or sand with much peaty dust and single sprigs of mosses underlay the solid peat and yielded the remains of the same Arctic *Apus* which was found in the ancient lakes of Hailes and Corstorphine, near Edinburgh, and near Auchtertool, Fifeshire. At one of the two recently uncovered sites, which may be called the Broughton lake, no Arctic plants and only a few of the remains of the *Apus* were obtained; but in the other, or Gayfield lake, great numbers of this crustacean were found, consisting of all the different parts of the animal—mandibles, body and tail-segments, the swimming-feet and portions of the carapace and appendages. Arctic plant-remains, chiefly leaves of *Salix herbacea*, likewise abounded. The fact that the lake-peat was not protected by any overlying deposit, but was found immediately below the vegetable soil, suggests that while the peat itself and its plants were at least in the lower part truly Arctic, seeds and leaves of Temperate species might in much later time have found their way into the upper parts of the peaty deposit, and thus give rise to an apparent commingling of plants indicative of extremely different conditions of climate. Such appears actually to have occurred. Mr. CLEMENT REID, to whom the plant-remains were submitted, finds that either two distinct plant-beds, or at least two different assemblages of plants, occur

at the Gayfield locality—the one showing Arctic, the other Temperate conditions. In the one case the occurrence of three species of dwarf Arctic willow indicates a climate like that of the North Cape, while in the other stones of the hawthorn and wild cherry point to a climate as mild as that now enjoyed by the Scottish Lowlands. A further fact of interest has been observed by Mr. BENNIE. In the deposits of the Gayfield lake there was found below the peat a bed of soft white silt or marl, containing a layer of freshwater shells, with seeds of pondweed and water-crowfoot. The shells are all well preserved, retaining even their epidermis, and the *Limnæa* are remarkably large. By carefully washing the shelly marl Mr. BENNIE succeeded in obtaining a number of ostracods, which have been named by Mr. SCOTT, naturalist to the Fishery Board of Scotland. These species have a wide range of distribution. None of them are peculiarly Arctic, and they throw no light on the climate of the time when the shell-marl was deposited. With regard to the mollusca of this shell-marl Mr. REID observes that they are confined to three widely distributed species, and that this want of variety is a usual characteristic of the shell-marls immediately above the boulder-clay, both in Scotland and the North of England. The pondweed and water-crowfoot have as wide a distribution as the shells.

THE interesting subject of curves in Mediæval Italian architecture has been again treated by Professor W. H. GOODYEAR in the *Architectural Record* for the present quarter. As in former cases, he produces many remarkable examples of horizontal curves which cannot be attributed to thrusts or settlements. From the Egyptian, Greek, Roman and Mediæval employment of them it would almost appear as if curved lines in masonry were as common as cambering in modern girders. It does not always follow that the use of the deviations from right lines is as apparent in all buildings as in the Parthenon. Professor GOODYEAR'S conclusions are shortly stated as follows:—(a) The Greek refinements were not confined to curves. They included constructive asymmetry in apparently equal dimensions of all members and spacings. They included an avoidance of all parallels in verticals as well as in horizontals. (Even the curves do not have the same amount of deflection on the stylobate which holds for the entablature.) These refinements consequently included an avoidance of all exactly perpendicular lines in favour of constructed leans, both outward and inward. (These facts are also found in the buildings of Mediæval Italy, as being due to construction and not to accident or carelessness.) (b) The curves of ancient architecture are not confined to Greek temples. They are also found in Egyptian and in Roman temples. (c) The curves of ancient architecture are not confined to curves in elevation, but they also include curves in plan. This holds even of the Parthenon, where the curves in plan of the alignment of the portico columns of the Parthenon are convex to the exterior. (d) The theories of optical correction, as explaining Greek curves, are best known to readers of English publications, but they are not favoured by BOUTMY, the leading French authority on this subject, nor by the German art historians like JACOB BURCKHARDT and SCHNAASE. (e) Neither PENROSE nor any other authority has ever antagonised the view that an effect of "life" and beauty was one purpose of the Greek curves, and PENROSE has expressly mentioned this explanation. (f) It may also be mentioned that HOFFER and BOUTMY have supposed the purpose of the Greek curves to have included that of exaggerating dimensions by artificial effects of curvilinear perspective. Artificial effects of perspective were certainly intended by other devices used in Mediæval Italian churches, and there are, in Italian churches, some cases of bends in elevation (if not of curves) in which a purpose of perspective exaggeration seems to be clearly involved.

THE publication of the second volume of Mr. EDWIN O. SACHS'S work, "Modern Opera Houses and Theatres" (B. T. BATSFORD), due this month, will have to be postponed until June, on account of an unexpected delay in the process of production. The author has, however, in consequence, been able to include some plates of Mr. TREE'S new theatre lately opened, and also of the new Opéra Comique at Paris, which is nearly completed.

## THE ASSOCIATION SKETCH BOOK.\*

MEMBERS may come and members may go, but the "Association Sketch Book" goes on for ever. What is more, there are no signs of decadence. The plates in the latest volume will bear comparison with those in preceding volumes, both for style of drawing and interest of subjects. Facilities of communication have enabled the members to go beyond the usual routes, and in consequence there is no less variety than heretofore. But it is also satisfactory to find that the members do not consider England was exhausted by their predecessors, for nearly one-half the plates are devoted to English work.

Mr. BRYER supplies two plates of Cromwell House, Highgate, which is one of the best of the surviving seventeenth-century mansions in the metropolitan district, but the grey used is too faint for geometrical drawings. Mr. H. P. G. MAULE has no less than eight creditable drawings of WREN's portion of Hampton Court, comprising plan of state apartments, south-west and south-east elevations, garden and river fronts, sections of mouldings and entrance gates. They may be said to comprise the exterior of the modern portion, and we hope to see them supplemented by drawings as careful of the interior. It is not often so many plates of one building are found without showing signs of a diminution of interest in the work. The railings from 44 Great Ormond Street are represented by Mr. HEATON COMYN. They are excellent specimens, without any of the contortions which were introduced as tokens of loyalty to the House of Hanover. The Entrance Gates of Emmanuel Hospital, which Mr. A. J. RODDES has drawn, are a little earlier in date. In the controversy over the hospital they were among the work referred to as deserving of preservation. Mr. NEEDHAM WILSON's three plates of All Saints Church, Leigh, Wilts, have the advantage of indicating the works of different centuries. In the building timber is largely used, and the sections are particularly interesting. It is a model set, and worthy of imitation by those who wish to do a small building thoroughly. Mr. C. S. SPOONER has four drawings of Ely Cathedral, which entailed an enormous amount of work. Although he confines himself to the presbytery, they were all in pencil, and were evidently drawn with much precision. On another plate Mr. SPOONER supplies some details of St. Mary's, Worstead, and St. James's, Southrepps, in which flint panelling has been skilfully used. Mr. R. S. BALFOUR shows details of Higham Ferrers Bede House. He also gives a plate of one of the old houses in the Close of Salisbury, which still retain their dignity, and form a pleasing adjunct to the cathedral. His two plates of Montacute House contain a plan of the garden, and show the curious terrace and pavilion. The Granary from Steeple Aston is curious, for it is carried on timber beams which rest on circular piers. A very good example of old timber-work from Lavenham is given by Mr. SPOONER. Another timber structure, but of Italian style, is a screen and gallery from Christchurch Park, Ipswich. A plate from Hatton Hall, by Mr. DODS, shows details from a room over the entrance gateway.

Three buildings from Venice are illustrated. Mr. EAST gives an elevation of the hospital which was formerly the school of St. Mark, a building with some fine ornamentation and coloured marbles. Mr. EAST's view of the Grimani Palace would have looked better if he had trusted to outline or had completed the details. The mixture of two styles of drawing is always unsatisfactory. The Church of the Frari, by Mr. CORLETTE, partly suggests Northern Gothic and partly Milanese; but owing to the difficulties of site the building appears to be subjected to lateral compression. It is one of the most admired of the Italian structures in red brick. The beautiful Font has been drawn by Mr. NICHOLSON from the cast at South Kensington. Two drawings of the pulpit in the church of St. Cesareo, Rome, are supplied by Mr. HART. The church and its contents are not much known. The pulpit is constructed of white marble inlaid with porphyry, green serpentine and cosmati mosaic. The evangelistic beasts are introduced and very quaint figures are made to support the columns. It is a curious example of mongrel Classic. Some details from a church at Miniato

are drawn by Mr. NICHOLSON, and there is a Fountain from a cast at South Kensington by Mr. C. C. BREWER. Very elaborate inlaid wood-work from Naples has been drawn by Mr. BALFOUR. La Zisa, Palermo, and the apse in the Duomo of Cephalu are Mr. HORSLEY's work, who also supplies some early decoration from a pulpit at Grado, which seems to be produced by Moorish artists.

In Mr. LOUIS AMBLER's drawing the cathedrals of Noyon and Soissons are contrasted. Both are important specimens of Mediæval work, for, as VIOLLET LE DUC has remarked, the builders have dared to raise them with means that seem feeble, and yet the repairs which were found necessary arose from fires, neglect or overloading. In Noyon especially, rubble which has little resistance has been mainly used. Mr. C. C. BREWER has a picturesque view of the organ-loft at Lamballe, which forms a curious combination of details. Still more pleasing are his views of the entrance to the cemetery at La Martyr, in Finisterre. The temptation to exaggeration has been avoided, and the figures of the Crucifixion are on a scale which allows of the importance of the architectural work being apparent. Two views of the Château of Rochefoucauld, at Angoulême, by Mr. BOLTON, show a characteristic Renaissance building which is adapted to its position at the riverside.

Among the Spanish subjects the most interesting are three of figure decoration which have no right to be included in the series. They are from paintings on the dome of the Sala del Tribunal, and are described as taken from French pencil-drawings in the possession of ANDREW OLIVER, and as apparently possession is nine parts of authorship in English architecture, as it is in English law, Mr. ANDREW OLIVER duly appears as author in the index. An architect's fame is fleeting among his brethren, and the editors as well as the possessor are not aware that the plates are reproductions of careful drawings made by JULES GOURY, who co-operated with OWEN JONES in the noble work on the Alhambra. For the benefit of those concerned it may be useful to give JONES's description of the paintings, as there is not a word about them supplied in the Sketch Book, and the subjects are puzzling:—

Much difference of opinion appears to exist amongst the authors who have described the Alhambra upon the subjects of the three paintings which are found in the domes of the alcoves of the Hall of Justice. It is said by many that they are not the work of the Moors, but executed posterior to the conquest of Granada, by Spanish painters. This opinion is founded chiefly on the injunctions contained in the Koran, forbidding the representation of animated beings; but that this law was disregarded by the builders of the Alhambra is fully proved by the fountain of the Court of the Lions, and the bas-relief which forms part of a fountain now in the Alcazaba. The ornaments, moreover, which are introduced into these paintings are strictly of a Moorish character. Another strong presumption of their being the work of the Moors exists in the construction of the domes; the plaster ornaments round the curve and in the spandrels are original Moorish work, which the Spaniards in their restorations of the palace never attempted to imitate.

*Centre Painting.*—The subject of this painting is considered by the Spaniards to represent a tribunal, whence they have called this hall Sala del Tribunal. From the different colours of the beards and dresses of the figures they would appear to represent the heads of the tribes of Granada.

II. It is difficult to connect the several subjects of which this painting is composed into one probable story. The chief group, that of a Moor killing a Christian, may be taken as a strong presumption of the paintings being the work of a Mohammedan artist, as it appears unlikely that it would have been so represented by a Spaniard after the conquest of Granada.

III. It is quite impossible to offer any conjecture upon the subject of this painting, whether it be legendary or historical. One-half of the picture appears to represent a boar hunt undertaken by Christians, and the other half by Moors. The submissive manner in which the Christian knight presents his share of the spoil to his lady on his return, may be contrasted with the more commanding attitude of the Moor, as finely exhibiting the estimation in which women were held by their respective nations; notwithstanding the want of perspective and knowledge of drawing, there is much spirit in the details, and the female figures especially are most graceful.

These paintings are of bright colours, but in flat tints without shadow, and were first drawn in outline in a brown colour. They are painted on skins of animals sewn together, nailed to the wooden dome, a fine coating of gypsum forming the surface to receive the painting. The ornaments on the gold ground are in relief.

There are four drawings by the late HEBER RIMMER, mainly from Palma, Majorca. It was remarked by him that "a distinguishing feature of the Palma architecture is a double roof and clear passage of air," an arrangement which is carried out without loss of architectural effect.

\* The Architectural Association Sketch Book, Series III. Vol. II. Edited by William G. B. Lewis and John Begg.

Owing to the heat there is much blank wall-space, and the connection with Spain is suggested by heraldic insignia. Mr. HACK's Casa Monterey, Salamanca, shows very elaborate cresting and an unusual diversity of windows.

### MOTOR TRAFFIC.

AN excellent paper on this subject was read before the Society of Arts on May 12 by Sir DAVID SALOMONS, Bart., M.A., when several points were touched upon which are of general interest, although the paper is described as "chiefly technical."

The author commences by apologising for reading a paper on a "well-worn" subject, but the paper shows that he has touched upon matters which are anything but well-worn. He also discusses the subject in which he has special interest—the Patent Laws—and goes deeply into the abuses and injustice which exist in this connection. It is, however, impossible to summarise this part of the paper, and those who are interested in patent laws should read the paper carefully.

The chief lessons which are to be learned, says the author, from the study of the literature of the subject, old and new, are:—1. The want of originality of most of the later patents. 2. The fact that the design of the better road vehicles is gravitating towards those in existence between 1820 and 1830. These statements are qualified, of course, by the improved methods of construction made possible by the advance in engineering, and the better materials available.

He then goes into the reasons why the horse-power required by motor vehicles is greater than that when a living horse is employed. He first shows that the reason greater power is required on a rough road than on a smooth one is that the wheels tend to push themselves into the ground before surmounting an obstacle, and he shows that a horse drawing a cart helps to pull the wheel over the obstacle because the point of application of the force is above the axle of the wheel and in front of it. The self-propelled vehicle is likened to the case of a horse pushing a vehicle from behind, when the action would be one of driving the wheels more into the ground. He further points out how a horse uses its weight as well as the anchorage obtained by its feet on the ground while drawing a load. The undulatory motion of the body shows this. The body is raised, independent of the kind of road, &c., and in falling again the weight is used to move the load forward. This is why a heavy horse can pull a greater load than a light one of equal strength.

He then passes on to pneumatic tyres, and shows that they are the ideal method of reducing the draught on a rough road, by allowing the obstructions to sink into them, and preventing the load having to be raised. He points out the great mechanical disadvantages, one of which is that due to the heating of the tyre if the load is heavy. This may, no doubt, be novel to some. He attributes it to probably either the heating due to the successive compressions of the air, or to the air having to pass through the small opening in the tube where it rests on the ground, as well as to the friction generally. Solid rubber has been used frequently in these cases with great success.

He mentions, in passing, the advantages of pneumatic axles, but says they are not satisfactory as yet.

Returning again to the power needed, he very properly points out the disadvantages of motors which will not exert a large force at a slow speed, and therefore makes complicated gearing necessary, and also points out the necessity for the continuous running of oil-engines.

The electric motor and the steam-engine are the two motors which possess a large starting effort, and the oil-engine is out of the question for this purpose. The maximum horse-power required while hill-climbing or traversing a rough road is far greater than the average, and it is then that the advantage of the two forms mentioned comes in.

He (Sir D. SALOMONS) gives it as his opinion that steam is by far the most suitable and advantageous for real work.

Sir DAVID SALOMONS, we think, rather lets his enthusiasm for steam carriages run away with him when he imposes the condition of running—that the car should go at the same rate, say twelve miles, up the steepest hill that horses can

now climb. This of course makes almost every form but steam take a very second place. There is no doubt that steam has very many advantages under certain conditions, but to talk in a perfectly general way is we do not think fair.

The French manufacturers are gradually increasing the weight and strength of their vehicles, to conform more with the English patterns.

The unsteadiness of the oil-motor, especially at the lower speeds, is mentioned, and is due to the irregularity of the explosions and to the bad governing, and it is also clear that the engine will run steadier when the carriage is moving fast. With steam and electricity these are obviated entirely.

Sir DAVID then goes on to discuss the electric vehicles and storage batteries. He is of opinion that the weight is heavy and maintenance heavy, that they cannot be considered anything other than a luxury, and that benzine and steam are only a quarter the cost to run, without taking into account the cost of maintenance. He takes the supply of electricity at 3d. per unit, and brings the cost out to 4d. per horse-power hour. He says that electricity is at present useless for commercial purposes, and here again we think he goes wrong, owing to the general way in which the matter is discussed.

For town use, where roads are good, and for say parcels delivery, or an omnibus company, there is a great field for an electric system. In the first place, one man can drive with perfect ease, whereas with steam this is impossible in a London street and is not advisable with oil; thus there is a small saving of, say, 30s. per week. Then electricity can be produced at much less than 3d. per unit, not taking into consideration the charge made from central stations used for lighting, but from a small separate plant; 1½d. per unit is a reasonable figure for an engine working constantly charging accumulators, while as low a figure as 1d. per unit could be obtained. Thus, supposing a motor to be 3 horse-power average, the costs stand—steam-fuel, 3d.; wages, 1s. 4d.; electricity-energy, 4d.; wages, 8d.; the totals being 1s. 7d. for steam and 1s. for electricity per hour. The extra 7d. will certainly pay for extra capital and the higher rate of renewals. The mistake has been made of supposing the fuel to be the only expense, and this mistake was once made in connection with electric-lighting stations, to the temporary advantage of electricity, and it appears that the same process must be gone through in connection with electricity for power purposes, but this time to the disadvantage of electricity. Sir D. SALOMONS admits, however, that the electric car is the most comfortable.

With respect to Sir D. SALOMONS' figures, they are all taken on the twelve miles an hour uphill condition, and we are therefore unable to agree with him. For instance, he says that 10 horse-power should be carried per ton weight of vehicle—i.e. the engine should be capable of giving 10 horse-power without injury. Four horse-power is quite sufficient for ordinary use when people are content to go uphill fairly slowly—i.e. six miles an hour.

Sir D. SALOMONS very rightly condemns the action of the financial people—i.e. company mongers—who state that great results are attainable with their particular form of motor or other apparatus.

Statistics are given, the results of which may be of interest as they are taken from the experiments and calculations of eminent engineers. TELFORD's results show that a force of 33 lbs. was required to move a waggon weighing 21 cwt. on a paved road, 147 lbs. on a gravel road, and on a broken stone surface 46 lbs. BABBAGE stated the friction or resistance of roads to be as follows:—Well-paved roads, 1-77 part of load; gravel roads, 1-35 part of load; fresh earth, 1-16 part of load. In fact, the ratio of the resistances to motion along a hard macadam to a by-road is about as one is to three.

Sir D. SALOMONS has no hesitation in saying that the steam-coaches of HANCOCK and others used in 1830 could be run to-day with perfect success, and that the improvements are due to better and cheaper materials.

In conclusion, this paper is quite a refreshing one after the many historical ones that have been read and after the "puff" which has appeared in many descriptions of special forms. The author's opinions are expressed quite frankly, and perhaps some of them are very much in advance of the present time. There is at least a perfect impartiality displayed in the treatment of the subject.

## THE GRAFTON GALLERY.

[BY A CORRESPONDENT.]

AS all the world is a stage and all the men and women merely players, it could hardly be possible for architects to be without some affinity with the actors. The aims of both are alike. The actor has by husbanding his resources to do much with as little expense as possible, and what else is the object of architecture? Every client wishes to make as brave a show as he can for a moderate outlay, and in a great many cases outward display is preferred to convenience. Why, for instance, had JOHN NASH at one time the monopoly of directing the great transforming act of which the scene extended from Regent Street to Regent's Park? Those who had charge of the Crown properties knew that he was able to bring theatrical experience to bear on building, and he certainly produced for his employers one of the showiest and cheapest displays which were witnessed in Europe. It is well known that when CHARLES MATHEWS the elder obtained an engagement in 1796 at Carmarthen to play in "The School for Scandal," JOHN NASH was the Sir PETER TEAZLE. The scene-painter was AUGUSTUS PUGIN. When soon afterwards NASH obtained his great commission, he kept the French artist by his side, and to the two of them London was indebted for its first and most memorable effort at beautification. MATHEWS wished his son to follow in NASH's footsteps, and in consequence CHARLES JAMES was apprenticed in the architect's office, but after the term was ended he preferred buildings made up of painted cloths to any structures he could erect. How often during the century which has elapsed since those days have the architect's office and the green room helped one another we need not relate, but enough is known to remove any misgiving about the duty of noticing the Exhibition of Dramatic and Musical Art which is now open in the Grafton Galleries.

It is the misfortune of the exhibitions in these galleries to be entirely controlled by amateurs. There is generally a happy thought inspiring them, but there is not the competence or experience which is necessary for its realisation. But as it was announced that theatrical people, with Sir HENRY IRVING as president, were to aid in "getting up" the new exhibition, it was concluded that there would be fewer drawbacks than usual. Nobody who was acquainted with stage folks could have an expectation of that kind. The ignorance which reigns behind the curtain on art, science and literature is appalling to strangers. Mrs. SIDDONS, who, like some living actresses, wished to pose as a superior being, tells us how she asked Dr. JOHNSON's opinion about her great predecessor Mrs. PRITCHARD, and the moralist said:—"Madam, she was a vulgar idiot; she used to speak of her *gown*, and she never read any part in a play in which she acted except her own." Mrs. SIDDONS professed to be shocked, but to her account she added, "I was afterwards assured by a gentleman, a friend of Mrs. PRITCHARD's, that he had supped with her one night after she had acted Lady MACBETH, and that she declared she had never perused the whole tragedy." Mrs. SIDDONS could not believe it, but she herself was not as thorough in her knowledge of dramatic literature as was desirable. What was true in the last century continues to be true, for we do not believe there is an actor or actress in London, however prominent, who would be competent to sustain an examination in one of SHAKESPEARE's plays such as is prescribed for candidates in the local examinations of the Universities. The same indifference is characteristic of their acquaintance with much else relating to the drama—everything that is not personal or their own is ignored. If these facts are remembered the incompleteness and errors of the Grafton exhibition will be understood.

Personal considerations have, however, gained the upper hand. The primary object of the exhibition would appear to be the advertisement of a few living actors and actresses by full-size portraits in oils instead of by posters, and the space which is left is occupied by odds and ends which drifted to Grafton Street by chance. There is no systematic arrangement, no connection between the objects. There is not one period of dramatic art which is sufficiently illustrated to satisfy ordinary playgoers. One can hardly believe so many omissions were accidental. To have three life-size paintings and two statuettes of the President may be only

an official privilege, but in a collection where there is not a scrap of paper to suggest what kind of men were SAMUEL PHELPS, GUSTAVUS BROOKE, JOHN VANDENHOFF, BARRY SULLIVAN, LEIGH MURRAY, SHERIDAN KNOWLES, ALFRED WIGAN, CHARLES DILLON, HENRY COMPTON, T. CRESWICK, HERMANN VEZIN and others, it would surely be more worthy to sacrifice one of the presidential likenesses if necessary than to allow so many lives to become as it were blanks. Where are the dramatists of the century? There were other scene-painters besides CLARKSON STANFIELD, and is it possible that an architect who designed a theatre never existed in Great Britain? It is only fitting, we suppose, that if among us we have actors and actresses who can contrive to be painted in full, then precedence should be given to them regardless of abilities, and we suppose the same rule applies to the music-hall performers we see here; but if no more than an advertisement were needed that fact should have been announced. Musical art as part of the title is an absurdity. LABLACHE, PUGNANI, PAGANINI, HERR HENTSCHEL, JOSEPH HOFFMAN, were not the only foreigners who flourished in England, and we must have had other native composers besides Mr. HENRY RUSSELL.

The portraits of which the director and committee somehow got possession were often puzzles to them, of which they could not understand the interest. Take, for instance, *Macready as Henry IV.* There is no doubt it is a portrait, but everybody knows there is a caste system in the drama, and the king's part is one which a star would avoid. How was it MACREADY accepted it? Of course, the catalogue does not tell, for the compilers demonstrate repeatedly they are not versed in the history of the English stage. For instance, it is gravely said the late WILLIAM FARREN created the part of Sir PETER TEAZLE, which means that he enacted the old husband in some state of pre-existence, nine years before his birth in this world. But the origin of the portrait was worth recording. In 1834 it was decided to give a spectacle in Drury Lane of a coronation, in which the Italian singers GRISI, RUBINI, TAMBURINI, with BRAHAM, PHILLIPS, IVANOFF and others, should perform. The costumes were as varied as the musical medley, and the orchestra, to do honour to the occasion, were obliged to wear large shirt collars like modern negro minstrels. As a prelude, scenes from the second part of "King Henry IV." were played, and the man who was the proudest on the stage was cast for the dying king. It was a solemn mockery, but MACREADY went through it, and it helped to embitter him against the fate from which he could not escape. When the history of the picture is known a new interest in the subject arises. Near it is a terrible parody of an Italian *Holy Family*. Was it worthy of a theatrical directorate to admit such a profanity as *Sheridan, his Wife and Child*? The author of "The School for Scandal," "Pizarro," "The Duenna," and the lessee of Drury Lane did not deserve that sort of treatment. SHERIDAN was scampish, but there was a level to which he could not sink. We may mention a third case. All who are acquainted with the subject of theatrical portraits or engravings from them know there was an artist who lived until 1832 named SAMUEL DE WILDE. The unhappy man has to pay dearly for his fidelity to the stage. Works against which he would revolt are ascribed to him. A number of actors, or amateurs, making obeisance to Sir HENRY IRVING with the words, "Please you, great sir, Bohemia greets you!" is credited to him as if he were living to-day. In another room we have, also by him, *Mr. Kemble and Mrs. Siddons*. It is a scene from "Macbeth," and as regards costume is more absurd than the representation of *Garrick and Mrs. Pritchard* in "Macbeth," for the lady is dressed in black with deep white trimmings, and wears a round black hat, while the Thane is in scarlet slashed with red. Now, the least acquaintance with the history of costume would be enough to convince the most unintelligent student that KEMBLE and Mrs. SIDDONS made it a boast to have never performed in the costume which was adopted by their predecessors. They began their reforms with "Macbeth." The picture, moreover, is not in DE WILDE's style; but we are afraid one style is the same as another to the Grafton committee. The *Head of Jack Bannister*, which belongs to the President, is described as by REYNOLDS. It is manifestly by LAWRENCE. It is also plain that the sup-

posed portrait *Inigo Jones* does not represent the architect. The subject was evidently a young courtier of the time of CHARLES I., who "made-up" after the king, while at the time JONES was at least sixty. There is also no resemblance with Mr. BUTLER's portrait, which has been often engraved. Another picture, called *Charles Kean as Richard III. and Wallack as Buckingham*, is no less of a puzzle. We do not believe that WALLACK ever appeared as second to the younger KEAN, but that is of no great importance. We see RICHARD talking to another man on a tented field. The President of the exhibition has his name on an edition of SHAKESPEARE; we should like him to point out for the benefit of students in what scene RICHARD and BUCKINGHAM are supposed to hold converse on the battle plain. According to the drama they last met in the Court, when the duke begged the king to keep his promise and grant him the earldom of Hereford. The picture apparently depicts either the last meeting between RICHARD and CATESBY or of the king and NORFOLK. There is a very fine portrait by HOPPNER, *Mrs. Michael-Angelo Taylor as Miranda*. Was the wife of the worthy member of Parliament an actress and when did she appear in the "Tempest"? It is generally understood the play was long neglected until MACREADY's revival. We believe the portrait is in no way theatrical, and is simply one of a lady who is supposed to be walking near the sea, to which the title "Miranda" has been affixed by accident. We need not proceed further in pointing out the weakness of the exhibition. Fortunately there are some objects over which the committee could not exercise any judgment, such as engravings with titles, play-bills and well-known paintings. The latter, on account of the miscellaneous and disorderly exhibition, appear deprived of much of their interest, but they are still worth attention.

There is a portrait of SHAKESPEARE by JANSSENS, and another of BEN JONSON which few will care to notice. The history of the British drama may therefore be considered as unrepresented until the reign of CHARLES II. There is a superfluity of engravings of NELL GWYN, and a painting which suggests her competence to play tomboys. The most interesting example belonging to that time is a pastel portrait which we would fondly believe is a record of THOMAS BETTERTON as a turbaned Turk. PEPYS believed he was a player who could not be valued enough. He championed one side in a contest that is still going on. In SHAKESPEARE's time most actors used to "mouth," and the practice has continued to our day. If anyone is eager to know what HAMLET desired when he wished to hear his lines spoken "trippingly on the tongue," he must go to Paris. Diction in HAMLET's and the French sense is unknown among us. BETTERTON took advantage of the French habits of the Court after the Restoration, and tried to naturalise it in London. "Conversation SHARPE" therefore looked on him as a pioneer. In a letter to HENDERSON, who was JOHN KEMBLE's great rival, he said:—"I think I have heard you remark that periodical changes have taken place in the taste of the audience, or at least in the manner of the great performers. Sometimes the natural and spirited mode has prevailed, and then the dignified and declamatory. BETTERTON, eminent both in comedy and tragedy, appears to have been an instance of the first. Then came BOOTH and QUIN, who were admired for the last. GARRICK followed, restoring or reinventing the best manner, which you have also adopted so fortunately and successfully. Mr. KEMBLE will be compelled by the hoarse monotony of his voice to rely upon the conventional stateliness that distinguished GARRICK's predecessors, which is now carried to inimitable perfection by his accomplished sister." In a few words there is the history of English acting. It is a counterpart of what we see in architecture—a struggle between conventionalisms and freedom.

We see no painting to recall QUIN or BOOTH in the Grafton Gallery, but there are more portraits of GARRICK than of any of the living actors. We can trace him at various periods of his career until we see him posing to satisfy the good HANNAH MORE. "It was only off the stage he was acting," said GOLDSMITH, and the portraits suggest the truth of the criticism. How natural the little man appears in the scene from the "Alchemist" by ZOFFANY, or even in the last scene from "Richard III." by HOGARTH, if compared the view of him embracing a bust of SHAKESPEARE or when playing picquet with his wife. The head in the latter

hardly seems to be human. The scene from "Macbeth" suggests how GARRICK turned opportunities to account. Mrs. PRITCHARD was a big woman of the Bermondsey-Manning type, and GARRICK therefore beside her assumed the rôle of a puppet. His legs hardly appear strong enough to sustain him, and he seems as if about to tumble out of the picture. Mrs. CIBBER was of another physique, and accordingly in the scene from "Venice Preserved" he appears as rigid as if cast in steel. His dissatisfaction with Mrs. SIDDONS suggests that in his old age he was wearied with the puppet rôle, and if he could have found an actress like Madame BERNHARDT (whose Lady MACBETH is one of her most remarkable creations), GARRICK would have been likely to have given a new version of the Scottish king's character.

Whatever may have been the shortcomings of their elocution, if compared with GARRICK's, JOHN KEMBLE and his sister upheld the dignity of the stage. He displayed no more hesitation in correcting the pronunciation of the king than with one of his minor actors. But then inelasticity of speech and action was as much out of place as Greek temples in London streets and at park gates. SHERIDAN hit off the weakness of the stately tragedian when he advised him to introduce music between the pauses in his speeches in "Hamlet." In the Grafton Gallery we see not only the brother and sister but CHARLES KEMBLE also in HARLOW's *Trial of Queen Katherine*, there is the second version of LAWRENCE's *John Kemble as Hamlet*, in which the head appears to be less out of proportion to the infinitude of the sky than in the picture at the National Portrait Gallery, and there are besides sundry small drawings and engravings of him.

In his childhood EDMUND KEAN, by his pranks, deranged the witches' scene in "Macbeth" which JOHN KEMBLE had devised, and he was destined to afterwards disturb the estimation in which his elder was held by himself and his contemporaries. KEAN was a phenomenon that seemed to be in keeping with a period which was acquainted with the French Revolution and the poetry of BYRON. He was as uncanny as MARAT, as much of a son of earth as DANTON, as overpowering as a volcano. He was deformed and yet appeared to be the most graceful of harlequins, while his dexterity as a swordsman made people assume he was a gentleman. His offences startled society, but he was not afraid to make himself out worse than he was. He never forgot he was a stroller, and that innkeepers obliged him to pay for beer before it was drawn. But his training was less perfect than that of the ordinary stroller. KEAN was compelled to amaze people at all costs: to play tragedy, to dance and tumble, sometimes to box and fence in the course of a night's performance, and if, as frequently happened, he was hissed as RICHARD, he had to win applause by the tricks of a monkey, or his dismissal was certain. When after years of wandering, during which he had to carry his child and his properties on his back, Drury Lane rose at his SHYLOCK, he was still treated as a sort of slave. His sphere was limited, for there were tyrants in those days. JOHN HENDERSON succeeded in FALSTAFF, therefore so kindly a critic as Sir WALTER SCOTT considered that all his other parts smacked of sack and sugar; audiences expressed themselves in a different style. GEORGE F. COOKE was kept to IAGO and SHYLOCK. KEAN was supposed to resemble RICHARD III., and in consequence it was accepted that he was unfitted to play any character which was without physical or mental defect. What do we see in the Grafton Gallery? An unfinished but vigorous head of KEAN, by CLINT, probably as Sir GILES OVERREACH; a well-preserved painting of him as RICHARD III., an engraving and a sketch in the same character, and a little coloured plate as SHYLOCK. But what a blessing it would be to English audiences if a man with KEAN's gifts were to appear among us with a repertoire equally limited.

KEAN was never impressive but when in the mood. MACREADY endeavoured to be always as intense, regardless of circumstances. He was the most painstaking and thorough of players. But he was most successful in subjective characters, and the public, who were indifferent to soliloquies, insisted he was at his best in ROB ROY and VIRGINIUS. His face was not expressive, it was as heavy as TALMA's, but the French actor played to an audience that

liked to see nature overcome, and were more satisfied in knowing he had prepared a scale of intonations for his HAMLET than if he presented as fine a head as KEMBLE's to their observation. MACREADY also left little to the inspiration of the moment in playing, but there is no painting or drawing at the Grafton Gallery to suggest his appearance on the stage, except one of him as ROMEO in his boyhood and the HENRY IV. The men who had any claim to be considered as tragedians in the years which followed MACREADY's retirement are carefully excluded from the walls. True dramatic art is becoming less appreciated every year. The theory of its representatives in our time is suggested when we find a portrait of MRS. LANGTRY "on the line," while one of Mrs. STIRLING in her prime is skied above it. Such spectacles are enough to make every earnest playgoer regret his visit to the gallery.

English portraits, and the contrasts they would excite would not be favourable to our insular art. There is a smaller portrait of M. COQUELIN, apparently as the Avocat DESTOURNELLES in *Mlle. de la Seiglière*, which is exquisitely finished by M. FRIANT. The French and the earlier English pictures are some compensation for the obtrusiveness and self-seeking which have inspired so large a part of the collection, making it as incoherent as a modern burlesque or adaptation from SHAKESPEARE.

### NORWICH CATHEDRAL.—III.

THERE is no cathedral in England so old as Norwich, which has been subjected to so few alterations of plan. It is now what it was in the time of Herbert de Lozenga, a cruci-

If we consider the modern portraits as works of art, priority must be awarded to M. CHARTRAN'S *Madame Sarah Bernhardt*. The background is almost white, and the scheme of colour is kept down in order not to provoke too violent a contrast. That the subject appears rejuvenated will rejoice all who can understand in what the art of acting consists. M. MADRAZZO'S *M. Coquelin as Don César de Bazan* is also admirable. It is most skilful in all its arrangements, and yet has the effect of a work that was dashed off at a sitting. The committee have taken the precaution to keep the two apart from the principal modern

form building with a choir and apse. Evidently nothing was allowed to diminish the importance of the high altar, or to distract attention from it, for the altars which were set up in the chapels were not visible to a worshipper in the nave. The simplicity of arrangement has advantages especially with the ritual which is now followed in cathedrals, the only drawback at Norwich being the length of the nave and aisles, for the preacher's voice cannot be distinctly heard in all parts.

An Excursion Meeting of the Northern Architectural Association will be held to-morrow, the 22nd inst., at the Castle, Castle Eden, by permission of Mr. Rowland Burdon, J.P.

### ST. MARK'S SCHOOLS, FARNBOROUGH.

ON May 19 the Duchess of Connaught, who was accompanied by the Duke, laid the foundation-stone of the above schools, which are in connection with St. Mark's Church, Farnborough. The ceremony was rendered all the more interesting from the fact that her Royal Highness laid the foundation of the church itself nearly seventeen years ago, that being the first public act performed in England after her marriage. The religious portion of the ceremony was performed by Bishop Sumner, of Guildford; and General Bancroft, on behalf of the building committee, thanked the Duchess for her attendance. The architects of the schools are Messrs. Charles Smith & Son, of Reading.

### THE AUCTIONEERS' INSTITUTE.

THE ordinary general meeting of the members of the Auctioneers' Institute of the United Kingdom was held in the lecture-hall of the Institute, Chancery Lane, W.C., on the 14th inst. Mr. James Frederick Field, the president, in the chair. The Council stated in their report that ninety-seven new members had been elected during the year. The income amounted to 1,608*l.* 4*s.* 7*d.* and the expenditure to 1,330*l.* 9*s.* 10*d.*, leaving a cash balance to be carried forward to the next year of 277*l.* 14*s.* 9*d.* The President, in moving the adoption of the report, congratulated the members on the continued progress and success of the Institution. The great expansion of the business of the Institute and the costs incurred in the action taken by the Council for the protection of the Institute had caused the expenditure for the year to be heavier than usual. The examinations were now being earnestly taken up by students. Efforts had been made during the year to remedy the present unsatisfactory method adopted by the Inland Revenue authorities of receiving estimates of value for probate and estate duty purposes from persons not competent to value. It was the opinion of the Council that a considerable loss of duty was sustained in connection with this matter, and they hoped that a change would be brought about at no distant date. Mr. James Green seconded the motion, which was adopted. The retiring members of the Council were re-elected, and other routine business having been transacted, Mr. Frank Everill, past president, invested the President with a president's badge and chain of office, subscribed for by members of the Institute throughout the kingdom, and to be worn by each successive President during his term of office.

The eleventh annual dinner of the members of the Institute was held at the Hôtel Cecil in the evening. The President

occupied the chair, and the company included Sir W. T. Marriott, Q.C., Mr. Christopher Oakley, Sir A. Blomfield, Sir W. W. Karslake, Mr. Causton, M.P., Mr. Atherley Jones, M.P., Mr. Richards, M.P., and Mr. C. Harris, secretary. Sir W. T. Marriott, in proposing the toast of the evening, "The Auctioneers' Institute of the United Kingdom," congratulated the Institute upon the standing which it had attained. The President, in response, said that during his period of office an effort had been made to obtain a charter of incorporation, and although personally he was not satisfied that the achievement of that object would be a wise step for the Institute, it was hoped that such a charter would soon be granted.

### THE GREEK THEATRE.

THE last lecture on "The Greek Theatre according to Recent Discoveries" was delivered on Saturday afternoon by Professor Mahaffy at the Royal Institution, and was mainly devoted to an exposition, illustrated by pictures on the screen, and to a vindication of the views expressed by Dr. Dörpfeldt as to the structure and arrangement of the Greek theatre before it was modified by the Romans. It had long been held, on the authority of a passage in Vitruvius, that, while the Roman stage was about 5 feet above the level of the audience—of the area which included what we now called the pit as well as the orchestra—the Greek stage was raised to a level of 10 feet or 12 feet. That statement had caused infinite trouble and sorrow to the critic and historian, and had occupied generations of commentators. But a Danish scholar had recently expressed doubts as to the authenticity of a statement which had hitherto been held to possess unquestionable authority, and these doubts seemed to be well founded. Dr. Dörpfeldt had proved by actual observation that it was the top of the back scene, and not the stage itself, which was thus elevated, and it was this which had been misnamed the *logeion*. Great credit was due to Dr. Dörpfeldt for the scientific study which he had devoted to the question, and to the way in which he had demonstrated the transition from the old Greek form to that of the Romans. The passage from Vitruvius, or whoever was the writer, had been a fruitful source of error. In the Roman development the whole theatre was covered, the stage lengthened, and the old entrance heightened. It was the universal habit of the Romans to adapt Greek things to their own taste and use, and it was not difficult to reconstruct what was purely Greek from the Roman enlargement and modification.

### NOTES AND COMMENTS.

IN the last number of the Occasional Papers by assistant surveyors attached to the War Department is one describing the brickworks which were set up four years ago by the Royal Engineers at the Curragh Camp in Ireland. It was found to be impossible to obtain an adequate supply from private yards, and the reconstruction of the camp must be delayed indefinitely unless the authorities become brick-makers. Accordingly an expert was brought from England to report on clays, and he recommended an alluvial deposit which is between 3 and 4 feet in thickness. It is not entirely satisfactory, for it is without uniformity of texture, and is mixed with pebbles, peat and bog oak. When dried the bricks are heavy and dark in colour. In order to diminish the risk of shrinkage the clay has to be dug out some months before use and allowed to dry in high heaps with steep slopes. The clay has some Irish peculiarities, for the bricks from one kiln come out of a colour which is altogether different from those turned out of the companion kiln, although the same fuel is used in both, and there is no difference in the process. About 3 yards of clay are used in the manufacture of a thousand bricks, and the machine produces about 20,000 in ten hours. In the hacks of the T house there is provision for 300,000 bricks; but, as in other places, work is not carried on from the beginning of October until the end of March. The bricks are brought to the camp by two traction engines, and about 26,400 can be delivered daily in fine weather.

TRAFFIC of all kinds in this country increases so quickly there seems to be no way of meeting the requirements unless by elastic structures, and they have to be invented. There is scarcely a railway terminus in London which has not been enlarged, and in the majority of provincial towns there is a like demand for an increase of space. Sea traffic also demands more provision, and in many ports there is a difficulty in obtaining it. Not only must docks have a greater superficial area for the accommodation of vessels, but they must contain deeper water than formerly. It is a remarkable fact that the Suez Canal should exercise influence on dock companies throughout the world, but every increase of depth in that waterway has to be met by a corresponding increase in all large docks. The question arises, How is that depth to be obtained? To remove the existing bottom of a dock, and to excavate the soil beneath and reset the masonry would be not only costly, but the time needed for the work might cause a diversion of traffic, for dock managers say they have to contend with competition in its strongest form. Accordingly in several places the difficulty is met by pumping an additional quantity of water into the basin. In Liverpool and Birkenhead the arrangement serves, and it is now being tried at Limehouse. Mr. WOLFE BARRY proposes to adopt it also at Hull. In the most modern docks at that port the maximum depth is 22 feet 6 inches, and in order to receive vessels that can pass along the Suez Canal it is absolutely necessary to have a depth of at least 26 feet under all conditions, and a depth of 28 feet or 28 feet 6 inches may sometimes be required. It is therefore intended by means of centrifugal pumps to pour sufficient water into the docks from the Humber to make up for their shallowness. Authority to execute the works is being sought from Parliament, but as the docks belong to the North-Eastern Railway Company there could not fail to be many opponents to the project.

THE appearance of Lord KELVIN as a witness on behalf of the Bill is an incident which deserves to be recorded. His lordship said he had at various times given a good deal of attention to the question of the currents in rivers and estuaries. He had examined the plans of the proposed new works in connection with the Hull Docks, and had gone over the site of those works and considered all possible influences that they might have on the channels and currents. He did not think they would in any way injure the channel. In his opinion it was impossible that such works can largely modify for the better or worse the great variability of the shores and channel of the river Humber, which existed long before the embayment, and has largely depended upon the forces of nature. The straightening of a river frontage, so far as it would exercise any influence,

would probably be favourable to the north channel. The Humber will probably be better off, and there will be less obstruction after the proposed improvements. Lord KELVIN, however, agreed that in the event of its being shown that injury accrued to the Humber in consequence of the works of the North-Eastern Company, those who produced the injury should be made responsible.

SEVERAL fragments of stained-glass have been discovered by Mr. C. B. FOWLER in the excavations which he is conducting in the grounds of Cardiff Castle, and which probably belonged to the Dominican and Franciscan monasteries which formerly stood there. According to Mr. FOWLER, the pieces are generally of fourteenth-century period, though several of the patterns are of later date. The glass tints are mostly of jonquil and citron yellow, light greys, browns and greens, lined with a dark red. The glass was discovered near the foundations of the churches at the west end, about a yard and a half in area and 3 feet underground, the pieces being piled one over the other in a mixture of clay and old mortar. The glass is very brittle in consequence of its burial for such a number of years, but many of the patterns and tints are still discernible and represent animals, birds and foliage, among which are the leopard, eagle and dove, the ivy, vine, fig, maple and oak; also the fleur-de-lis. What adds to the interest of the discovery is that the churches of Glamorgan appear to have been deprived of the advantage of stained-glass.

IF allowance be made for the difference between the subjects, all that we have said about the first part of "Architecture of the Renaissance in England," by Mr. J. A. GOTCH, will apply to the first of "Later Renaissance Architecture in England," by Messrs. J. BELCHER and M. E. MACARTNEY. The two (published by Mr. BATSFORD) are as uniform as if they were to be bound together as one work. It is unusual to find such fidelity to a predecessor in the preparation of books, and Mr. GOTCH has reason to be proud of the spirit of imitation which inspires his two followers. But while we admire the modesty we do not believe it is altogether advantageous in the present case. People are now less disposed to be satisfied with pendants or companions which are exactly alike, and editors of series of books are compelled to recognise various modes of treating subjects if they desire the co-operation of practised writers who can be considered as authorities. It would not be difficult to introduce features which would impart character to the new venture, and enhance the interest of the plates. But not one novelty appears in the first instalment, nor is one promised in the prospectus. The subjects illustrated by Mr. GOTCH were often not known beyond the districts in which they were found, and he merited credit for his discoveries; but examples of Later Renaissance like the Ashmolean Museum, Radcliffe Library and Trinity College Chapel in Oxford, Peterhouse College, Somerset House, the Home Office, Admiralty, Ashburnham House, Greenwich Hospital, New Palace, Ham House, the Hall, Winchester School, Townhall, Guildford, which are among the examples in the first part, may claim to be more or less familiar to all who bestow attention on architecture. With buildings of the kind the photographers could hardly go wrong, and hence something is needed to demonstrate the necessity for the names of two architects appearing on the title-page. There is no doubt an introduction, and there will be descriptions, but in treating of buildings of the period neither history nor philosophy has much scope. The authors do not attempt to be more than compilers in the sample which is given. As it is not imperative to make all the parts of a new work alike, there will be consequently opportunities in the succeeding numbers to compensate for the shortcomings of the start. It is claimed for Later Renaissance architecture that it is a development, and is not merely imitative, but is full of vitality and vigour. We hope we may see in the next number some evidence that the authors believed those qualities could be exemplified in their manner of presenting the buildings, and that their subject inspired them to produce a work that was superior to its predecessor. The prejudice against continuations and sequels may be unwise, but it is universal, and it is not to be overcome by seeking after the closest resemblance to the original which can be secured.

SHEFFIELD MUNICIPAL BUILDINGS.—TOWER AND WEST FRONT.—ENTRANCE GATES.—RECEPTION AND DINING-ROOM.

THE Sheffield Town Hall, which is to be formally opened by the Queen to-day, stands upon a site almost triangular in shape, but the apex of the triangle is cut off, thus forming a short fourth side to Norfolk Street. The principal front faces Pinstone Street and is 200 feet in length, that towards Surrey Street being 80 feet longer. On the side next Cheney Row a part of the site still remains available for future extension.

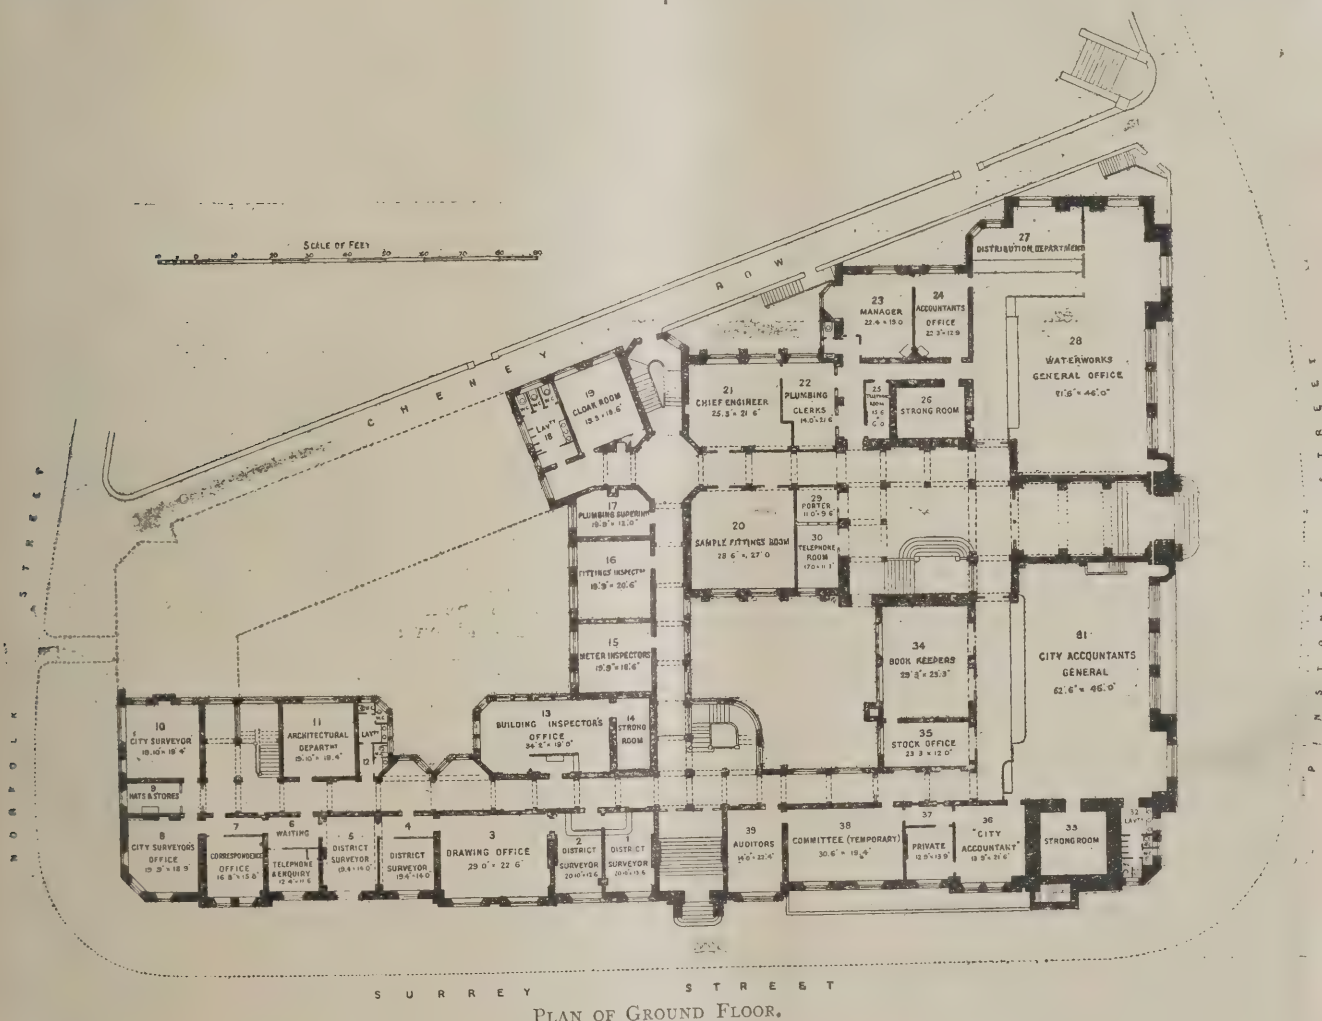

The main entrance, in the centre of the Surrey Street front, is 12 feet in width, a vestibule, 20 feet wide, leading thence to the hall, rather more than 40 feet square, from which rises the grand staircase. To the right and left of the hall are the offices belonging respectively to the water-works and the city accountant's department, the public offices of each department being fine rooms 46 feet in width, nearly 70 feet long and 16 feet high, both facing Pinstone Street.

room itself measures 60 feet by 40 feet, is 28 feet high and lighted by traceried windows upon three sides. A separate entrance and staircase to the public gallery are provided from Cheney Row.

On the second-floor are various offices connected with the different departments, and in a separate part of the building is a kitchen, with the necessary appurtenances, for use upon the occasion of banquets or receptions.

The tower at the corner of Norfolk and Surrey streets is 25 feet square and rises to a height of 200 feet above the pavement, measuring to the head of Vulcan on the summit.

The building throughout is faced with stone obtained from the quarries at Stoke Hall, about 12 miles from Sheffield. Internally the reception-rooms, council chamber and committee rooms have polished oak floors, the lower part of their walls is panelled in oak and they have decorated ceilings, that in the council chamber being the finest. The doors and other joinery throughout the principal floors of the building are also of oak. The grand staircase is 10 feet wide and entirely of marble, the pavements of the

That portion of the building fronting Surrey Street has separate entrances from both Surrey and Norfolk Streets, and contains on the lower ground floor the offices of the medical officer of health, the city surveyor occupying the ground floor, and the town clerk the first floor. The various departments are connected by two wide staircases, in addition to the staircase used in connection with the mayor's reception-room and the council chamber.

The mayor's three reception-rooms, namely, the reception-hall, the dining-hall and the mayor's parlour, are approached by the grand staircase and corridor, the latter being 160 feet in length and 10 feet wide. The rooms are divided from each other by solid oak partitions, so constructed that they can be easily raised into the roof, when the three rooms can be used as one, which then becomes 155 feet in length, 35 in width and 22 feet high.

The council chamber is approached from the grand staircase through a spacious ante-room, and is provided with a large cloak-room and convenient lavatories. The

vestibule, hall and grand corridor being of the same material. The walls of the hall and grand corridor are lined with marble and alabaster. In other parts of the building the corridors have floors of glass mosaic and a specially designed dado of antique glazed tiles. The secondary staircases are of York stone.

The various rooms and corridors are warmed by steam and lighted by electricity, the brass electroliers having been specially made from designs by the architect. That over the principal staircase is of bronze and is a fine piece of work.

All the principal offices are furnished and fitted in oak from the architect's drawings at a cost of nearly 20,000/.

Throughout the building there is much fine sculpture, the work of Mr. F. W. POMEROY, Royal Academy Gold Medallist. In the spandrels above the principal entrance are life-size female figures representing "Electricity" and "Steam." On each side of the vestibule are carved panels representing the various Virtues, the spandrels between the

arches being carved with flowers and foliage typical of the same qualities. In the hall is a fine carved frieze representing the destruction of the Dragon of Wantley (or Wharnccliffe) by Moor of Moor Hall. Above the door leading from the grand staircase into the antechamber is a fine panel illustrating the text, "Be ye wise as serpents and harmless as doves," while all round the upper part of the staircase are figures and emblems representative of the Sheffield trades. In the mayor's parlour is a fine chimney-piece containing a panel carved in alabaster, with figures representing "Religion" and "Prudence," while below is an illustration of the text, "Unless the LORD build the house their labour is in vain that build it. Unless the LORD keep the city the watchman waketh but in vain." In various parts of the building are carved shields bearing the coats of arms of the city, the Duke of YORK, the Duke of NORFOLK, the Cutlers' Company and the Earl of WHARNCCLIFFE.

Returning again to the outside of the building, there will be seen above the principal entrance the city arms, supported by heroic figures of Thor and Vulcan, while in the gable above is a life-size statue of Her Majesty the QUEEN (carved by M. RAGGIE), with the royal arms of England overhead and symbols of her sovereignty of the seas on either side. In the central block of the Surrey Street front are statues representing "Peace" and "War," and over the first-floor windows are heads of animals symbolical of India and the Colonies. In the upper part of the council-chamber gable towards Cheney Row is a statue of "Justice."

The architecture of the building is distinctly modern in character, and of the style known as Renaissance.

The comparative smallness and great value of the site prevented any considerable setting back of the various fronts for architectural effect, for which reason, and in order to counteract the peculiarities of the Sheffield climate, it was necessary to treat the building simply and broadly with comparatively small projections, and keeping the various mouldings and cornices somewhat flatter than usual. The whole of the materials, including the various coloured marbles, are British, and, as far as possible, local. The building has occupied over five years in erection.

The architect of the building is Mr. E. W. MOUNTFORD, of 17 Buckingham Street, Strand, a member of the Council of the Royal Institute of British Architects, and late President of the Architectural Association; amongst whose other recent works may be mentioned the Battersea Polytechnic, the Battersea Town Hall, the Northampton Institute, Clerkenwell, and St. Olave's Grammar School, Southwark, and who is just commencing the new museum and technical schools for the Corporation of Liverpool.

Additional illustrations of the Sheffield Municipal Buildings will be published next week.

Athens last year Professor Dürm and M. Magne had already made their reports. The former had gone very fully into the question of the defects and remedies, and his report was a valuable contribution to the study of the subject. That of M. Magne was a brilliant and well-illustrated memoir on the construction and ornaments of the temple rather than a more technical report on the defects and remedies; but he called attention to one very important detail, namely, the instability of the angles of the pediments. The local committee had already made arrangements for several 14-foot architrave stones being prepared on Mount Pentelicus.

The part of the temple which demanded the most immediate attention was the hexastyle portico of the Posticum. The state of the Posticum was such that it was impossible to execute any satisfactory repair without replacing at least five of the architrave stones. Of the six columns composing the portico, four only were free; two of them were more or less embedded in the mass of masonry containing a staircase which was once surmounted by a Turkish minaret. This mass secured the southern columniation. The architraves supported by the four free columns consisted of twelve stones. Of these twelve, only five were free from very great defects; but if five of them could be replaced with new material, two could be so pinned together to their neighbours that they might be supported sufficiently well. The worst defects were on the eastern side of the portico. With one exception the western stones were sound, which was fortunate, as they supported the portion of the Panathenaic frieze still left on the temple. With regard to the defective one, namely, that which once connected the north-eastern column with its neighbour, the simplest remedy would have been to replace it with new; but its removal would endanger a portion of the precious sculptures, and it would have to be keyed to a new stone placed alongside of it. Professor Dürm, in his report, suggested that the reason of this part being in so much worse condition than any other, was that the original builders had used for an interior part of the fabric a very much worse material than they had provided for the exterior. It was true that the marble of these architraves was more streaky than could be found on the exterior; but streaky marble of similar quality had endured well on the Temple of Jupiter Olympius. Another and more effective cause could be assigned to it, namely, fire, which had consumed all the inflammable part of the structure, and had very much calcined the whole of the superstructure of the Posticum, as the state of the surface of the marble showed. It had also weakened the lintel of the great western door, and some of the columns of the Posticum, especially on the eastern side, had also suffered. Many portions of the capitals and of the architrave stones in this part retained traces of iron plugs, which could only have been used to fix some material for the purpose of repairing the surfaces which had been split off by the action of fire. This completely explained why the architrave stones of this portion of the building, although much less subject to ordinary weather vicissitudes, had become so much more cracked than those of the peristyle. A large piece from the middle intercolumniation fell down in the earthquake of 1894, split off apparently at an ancient flaw. The course of deep stones above the architrave, which formed the back of the Panathenaic frieze, and ranged with it in level, was also very much cracked and dislocated, so much so that only two pieces in the whole length, very little more than a quarter of the whole, were in a fit condition to be retained. These pieces, however, were neither so difficult to handle nor to replace as the main architrave stones, which had a length of about 13 feet 9 inches each.

The lecturer then referred to the difficulties attending the removal of the condemned blocks and fixing those which were to replace them, and showed by the aid of diagrams how the operation could be performed.

With regard to the lintel of the great western door, the two ends remained in the wall, but the rest was gone, and the place was occupied by an exceedingly unsightly brick arch. This, it was hoped, would be replaced by marble; but there was not the slightest prospect of a 30-foot beam being found, nor could it be brought to Athens with existing appliances. The plan recommended by the lecturer, and accepted by the Athenian committee, and by Mr. Penrose's French and German colleagues, was explained by a diagram on the wall.

The insecure condition of the angles of the temple was to be traced to the great overhanging stones which supported the angular acroteria having a tendency to slip downwards and drag the neighbouring portions of the superstructure with them. The worst crack in the architrave was over the north-west angle column, where, owing to the fall of a large piece at the corner of the abacus, the bearing of the outer stone of the architrave was reduced to little more than a point.

In describing the north-west front, he said that between the fourth and fifth columns, reckoning from the south, a crack through the architrave had been produced by a cannon-shot, and the abacus of the fourth column had been so much shattered that it gave a bearing to no more than about half the thickness of the architraves which rested upon it. The

## ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last, Professor Aitchison, A.R.A., president, in the chair.

Mr. F. C. Penrose, F.R.S., read a paper on

### The Parthenon and the Earthquake of 1894.

Mr. Penrose said he had undertaken to describe the result of his recent examination of the Parthenon, the object of which was to advise the Greek Minister of Public Instruction, and the Archaeological Society of Athens, as to certain repairs which were required in consequence of the damage done to the building by the earthquake of 1894. Three international consulting architects—namely, Mr. Penrose himself, Professor Dürm (of Carlsruhe) and M. Lucien Magne (of Paris)—had been appointed to confer with a local committee, presided over by M. Cavvadias, the Government Superintendent of Antiquities, and consisting of several Greek members of the Athens Archaeological Society and some associated members, including Dr. Dörpfeld, M. Troump, a resident French architect, and the Government engineer, M. Balános, who was to superintend the repairs.

Having referred at some length to the principal events which had reduced the building to its present insecure condition, Mr. Penrose went on to say that when he arrived at

exfoliation of iron cramps connecting the architrave stones at the top had also injured all but one of the vertical joints, but beyond the breakages of the large splinters which had fallen the injury at these places from the iron cramps did not seem likely to extend. Among the diagrams shown by the lecturer was one illustrating the curious construction of parts, and another showing how the angles could be secured from slipping by connecting the great horizontal corner-stones by means of strong gun-metal cramps with the main cornice at a sufficient distance, so as to provide an adequate amount of weight to resist the tendency to slip.

Few of the new stones proposed to be introduced would make any difference in the general view of the temple, and scarcely any of the steel or bronze-work; and the new stone could be stained with copperas, as he had shown by experiment, so as to be almost indistinguishable from some of the old time-stained marble.

Professor E. Gardner said he first became acquainted with the Parthenon in company with Mr. Penrose. He was in Athens at the time of the earthquake in 1894. Some years before that an international commission was appointed to consider from the æsthetic point of view the restoration and clearing away of some of the added parts. The earthquake was not answerable for the cracks, as a minute examination failed to reveal new ones except in one or two minor instances. In fact, the earthquake did some good in calling attention to the necessity of strengthening the columns and the precarious state of certain portions of the building. Regarding the Turkish minaret, the great width of the door and the columns, he asked Mr. Penrose some questions. Nothing was more discordant to his mind than the rebuilding of the mangled columns, and the attempt to build up the old pieces had been very disastrous. It would be impossible to rebuild the whole, as there was not sufficient material, and to rebuild a few blocks would spoil the symmetry, and he hoped Mr. Penrose would ask for the demolition of those that had been re-erected. The jambs of the western door he thought might be removed for a time because the blocks had long inscriptions which would then be accessible. The staircase in the lower part of the minaret might possibly have belonged to a Christian church. It afforded a great deal of support to the architrave. Some years ago people wanted it removed as a later addition, but considering the support it gave it was considered dangerous to do so. He thought they would all be reassured after noticing the numerous cracks and the seemingly inadequate support of certain of the blocks when they heard from Mr. Penrose that the building could be repaired so easily.

Mr. R. Phené Spiers proposed a vote of thanks to Mr. Penrose. He felt, when he visited Athens, that all the measurements that were to be taken had been made, so he therefore made water-colour drawings of the ruins, every view of which seemed so different. He found, on examination, that later views showed very little change in the structure since he was there. He wanted to know the actual cause of the discoloration of the marble. Was it iron rust, decay of stone, or other causes?

Mr. T. J. Willson seconded the vote. He thought the whole architectural world was to be congratulated on the comparatively small extent of repair and restoration which the Parthenon required, and the small amount of damage done by the earthquake, which was not so bad as had been anticipated.

Mr. John Hebb agreed with the general procedure which had been employed; nothing could be better, he thought. The colouring of the marble to make it have the appearance of old work was wrong. The colouring should be left to nature, and very shortly the new work would be in harmony with its surroundings. He appreciated the ingenious way in which architraves had been raised, and the care with which the work of restoration had been carried on in other ways.

Mr. Hugh Stannus suggested a more general use of cement as a preservative.

Mr. A. Payne submitted photographs which were taken twelve years ago in order to suggest the progress of deterioration. He pointed out the difficulty of re-erecting the parts of the broken columns, as of course the bedding surfaces would not correspond and the outlines of the column could not be true.

Mr. J. M. Brydon took the opportunity of mentioning the difficulty which was still attached to the peculiarity of the frieze being placed in a position where it was not visible. One of the theories which had been suggested was that originally the frieze was intended to be more visible, but that the supply of funds caused outward parts to be erected which concealed it. He need hardly say he did not believe in that theory, but it was difficult to hit on one which would be convincing.

Mr. Penrose, in acknowledging the vote of thanks, shortly referred to the points raised in the discussion. He explained some of the precautions adopted by the committee, but as regarded the stains he believed they arose from the iron which was an element of the Pentellic marble. By the pointing with a dull cement it was possible that there would be no increase in the stains.

## EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual general meeting of the Edinburgh Architectural Association was held on the 12th inst. in the Royal Institution, Dr. Rowand Anderson, the retiring president, in the chair. The following were elected for the forthcoming year:—President, Mr. Thomas Ross, F.S.A., Scot.; vice-presidents, Mr. John Watson, architect, and Mr. James Bruce, W.S.; hon. secretary, Mr. T. Fairbairn; hon. excursion and syllabus secretary, Mr. A. Hunter Crawford, architect; treasurer, Mr. John Johnston, C.A.; and members of council, Messrs. J. A. Carfrae, J. D. Cairns, the Rev. P. M. Herford, David Robertson, A.R.S.A., William Rae Macdonald, and R. Morham. It was reported that at this time the membership stood at 302, which was practically the same as at the end of the year 1895-96.

Dr. Rowand Anderson then delivered the following valedictory address:—In the few remarks I have to make before resigning my office of president I do not feel I can do better than recapitulate and, if possible, emphasise some of the questions I have dealt with from this chair, firstly, because, if I have anything to say to you, it is better that I confine myself to such subjects as I have thought about; and secondly, because I consider that such questions as I have dealt with are of importance and should be discussed from time to time by our Association as an aid to forming public opinion on matters that every community must deal with periodically.

When I took office two years ago one of the questions prominently before the profession was that of education, combined with efforts to make our occupation a close one. I explained my views fully to you, and I have heard nothing on the other side since to lead me to think differently. At the bottom of this controversy lies a misconception of the nature of our business, as compared with the professions of divinity, law and medicine. The divine has to subscribe to a creed, his historical and philosophical knowledge of which must be tested. The lawyer has to administer the laws of the country, according to the fixed principles and form of those laws, and his qualifying knowledge of such must be ascertained. The physician or surgeon has to deal with disease in all its forms, and none can be successful unless he has acquired an intimate knowledge of the anatomy and functions of the body and all its parts, as also of the experience of the past and the various methods used in combating disease. They have not to provide what the public wants, in the same sense as a picture-painter or dealer, or as an architect in designing a house or other building has to meet the individual wants and desires of a client.

You go to men of the professions I have named for what they are certified to possess and to be able to do, and not to dictate to them in what manner you are to be spiritually consoled, or to have the law administered or modified in the settlement of your affairs, or to have your physical troubles alleviated, so that in each case your own wishes may be met. The public deal with us on a totally different footing. While it is true that a client may go to one architect rather than to another, because he is known, or believed to be a better educated man in his work than others, yet, taken generally, the architect is but the interpreter of the public idea of art at any given time, and he has to provide what the public wants and is prepared to pay for. No compulsory examination or diploma can alter this. The law cannot and will not protect the public from bad art, because the public can and must at all times protect itself, and if it gets bad art it gets what it wanted, and the only thing it is able to appreciate. The one hope for art, and I speak of art in its widest sense, is an educated public. When the public are able to distinguish good from bad, and when they come to look at art not as a question of mere ornament and as a thing apart from structural and functional truth, then the bad architect will naturally disappear, and no artificial aid will perpetuate his kind or find work for him.

While little has been heard lately of converting the architect into a certified professional man, our friend, the registered plumber, is still well to the front, and he is now asking the legislature to pass a Registration Bill as a means of protecting the public health against the ravages of the incompetent man. How the passing of such an Act can do this I cannot comprehend. If the legislature could insure plumbers good prices for their work there might be something in it. That registration will prove that a man is competent, and be a guarantee to the public that good work will be done, is a fallacy; nothing can make a good plumber or any other tradesman but employment on good work and under a competent foreman and master, and receiving proper payment for his work. Stuffing a lad's head with a lot of data about his work will no more make a good plumber than attending a class on navigation will qualify one to take a ship to sea. So far from the public requiring to be protected against the inferior plumber, it is the respectable plumber who requires to be protected against the public. The keen and excessive competition which is stimulated by the demand for cheap work; the pitting of men of substance, experience and character against men who have no

these qualifications is the real cause of bad work, and until that state of things is altered the registered plumber will only intensify the present unsatisfactory state of things. This claim to protect the public health is rather an arrogant one. The plumber is only a link in the chain, and, if registration is necessary for him, it is equally so for other tradesmen. The mason and the Irish labourer who lay the drains are in every respect as important as the plumber as far as health is concerned.

The State cannot protect the public from the incompetent tradesman unless it controls both parties to the contract, that is to say, the work and the price to be paid for it. To attempt to do this would, of course, be an absurdity. I have looked over the Plumbers' Registration Bill, and all I can see in it is an arrangement for the appointment of secretaries, treasurers and auditors, and the collection of fees, but nothing whatever that will add to the protection of the public and insure a higher standard of work, and for this very good reason, which knocks the bottom out of the whole thing, that no provision can be made for insuring payment for good work. But the State can do, and is doing much that is already bearing good fruit in improving everything that concerns public health and structures of all kinds, by the appointment of public health officers, the passing of Public Health and Police Acts, and by the powers conferred on health officers, burgh engineers and sanitary inspectors. The enforcement by law of these Acts alike against the public, the plumber and the architect is the true and only way of bringing about a better state of things.

While I am entirely opposed to all artificial distinctions of hall-marking of a man because he has undergone an examination on subjects which are admittedly not those that test the real qualifications that fit a man for his calling, I am all in favour of education. Give every young man a fair opportunity of equipping himself for his life's work, then let him swim or sink on his own merits or want of them. The young man who has good stuff in him will educate himself up to the standard of his time, because he knows that to do so is the only passport to success. But you must provide the means of his doing this, and as far as art work is concerned, that is the reason for establishing our applied art school. Every young man cannot get into a workshop or office where good and artistic work is done. He may, and often does, drift into a place where he learns little or nothing, but that can be to a large extent rectified by attending this school, and if there is earnestness as well as ability in him he will get every help and encouragement. This week three students are leaving having been awarded travelling bursaries, and I have such confidence in them that I feel sure they will submit for inspection an amount of work which, both for quantity and quality, will show that the committee have selected the right men. Two of these students are architect's assistants, and one a furniture designer, and it cannot be too widely known that our system of education makes no distinction between the different occupations of the students; the rewards and prizes at this school can be held by any art worker. Merit is the sole title that we recognise.

Now that I have said something about the student, I have something to say about the public. Our Association, gentlemen, does something to educate the public. We do not exist like other Associations for the benefit of the architect only, our strong point is that we exist chiefly for the benefit of architecture and its allied arts. The association of a large number of non-professional members in our midst is a feature that I hope will never be surrendered. The more we can interest the public in art the better for us and for art, and if all other institutes and associations will do as we do, the architect and his work would be better understood and appreciated.

The Saturday afternoon excursions, which are largely taken advantage of by our non-professional members, are most enjoyable and are always interesting and instructive. The unflinching courtesy with which we are always received shows that the noblemen and gentlemen who throw open their places to us know that we do not come out of idle curiosity, but from a desire to learn from and to appreciate all we see. This year our special thanks are due to the Earl of Hopetoun, Lord Torphichen, Mr. McKelvie of Hatton, Messrs. Scott, Bruce & Glover, W.S., and Mr. W. W. Robertson of H.M. Board of Works. We have still two excursions before the season closes, and on each occasion I can promise all who come a very pleasant and interesting afternoon. This is an eventful year in the history of our country; it marks a long period of progress, prosperity and comparative peace under the beneficent reign of our gracious Sovereign Queen Victoria, and in all those benefits we have shared. A great advance in architecture and, indeed, in all the arts, has taken place during Her Majesty's reign, and much of the improvement may be attributed to the direct influence and fostering care of the late Prince Consort. This Association is, therefore, in common with all the subjects of the British Empire, greatly interested in the question of the day as to the most fitting expression to be given to this thanksgiving and jubilee for the long and prosperous reign of her most gracious Majesty. I am aware that the suggestion which commends itself most highly at this time is the equipment or

endowment of institutions for the relief of the sick and suffering. But apart from the fact that infirmaries, hospitals and kindred institutions command at all times national sympathy and support irrespective of any special occasion like the present, I would like to point out that this is to a certain extent beginning at the wrong end.

There is a well-known proverb which says that prevention is better than cure. Applying it to this case I say do something to keep the people healthy and happy in mind and body, and there will be less need for infirmaries, nursing associations, &c. I would, therefore, like in a word or two to repeat what I dwelt on at greater length in a former address regarding the provision of a suitable place for amusement and relaxation for the masses of people whose means do not admit of their procuring such for themselves.

In my opinion nothing could better mark this year of jubilee or be more in accordance with the expressed wish of Her Majesty and the touching letter of the Princess of Wales, in which she pleads that when schools, hospitals and other institutions have been properly provided for, the poor should not be overlooked, than the inauguration of a movement to bring into the lives of those whose means are only sufficient for the bare necessities some of that brightness and pleasure which are the outcome of comfortable and cheerful surroundings and innocent recreation. I think that the institution of a great free place of recreation for the people would be found to have the most potent influence not only in preserving them from many habits which lead to loss of health, but in refining and educating them and in promoting that cheerfulness and contentment of mind which is the enemy to all social disturbances, and I do not think that the municipality could in this year of jubilee enter on any scheme which would have more far-reaching or more beneficent effects.

We hear much at present about the encouragement of music in our midst, but I submit that this can best be done by making music a part of the daily life of the people, and that can only be accomplished by having some vast place to which crowds of men, women and children can resort, and have their little social parties and listen to music without any charge for it. The municipality ought to maintain a first-class orchestra for this purpose. The establishment of such a place of recreation for the people is, in a climate such as ours, a distinct and crying want in every city; and the revenue derived from the sale of refreshments, from bazaars, military tournaments, flower shows, &c., would be sufficient to cover current expenses.

This evening terminates my occupancy of this chair, and, in saying good-bye to you, I have to introduce to you our chosen successor, Mr. Ross. Mr. Ross has long been a loyal and active member of this Association, and is well known not only to all of you, but to a very wide circle outside. His *magnum opus* which he prepared in conjunction with Mr. McGibbon, another valued friend and member of this Association, will long remain a monument of industry and research. It is now having, and will continue to have, an important influence on Scottish architecture. When Mr. Billing's work on "The Baronial and Ecclesiastical Antiquities of Scotland" was published, it disclosed the existence in Scotland of a class of buildings unlike any that had hitherto been illustrated. The publication of this work coincided with a period of great agricultural prosperity and high rents, as a result of which many old houses were enlarged and new ones were built, and all were more or less in imitation of the buildings illustrated in Mr. Billing's work. It cannot, however, be said that this work led to the erection of buildings which mark the recovery of a lost art, or that the buildings erected at this time were in any way expressive of the social or political state of the time, because all the buildings illustrated by Mr. Billing belonged to a time when a house was more or less a castle, a building to keep people out, not one to invite you into, and they were, therefore, not fitting types for buildings erected in a time of peace and prosperity. A great opportunity for a revival of art was thus lost. The great merit of the work on Scottish architecture, by Messrs. McGibbon & Ross, is that it illustrates a large number of buildings not noticed in Billing's work, buildings eminently Scottish, and at the same time eminently domestic in their character. These are the buildings that ought to be studied with a view to their application to present-day work, and if we in Scotland are to develop a domestic art having a distinctly local colour—and we ought to do so—it will be largely owing to the publication of this valuable work.

Gentlemen, I have to thank you for the courtesy and consideration you have at all times extended to me. To the permanent officials, our honorary secretary and treasurer, I and we owe a great debt of gratitude. Their continuance in office, with their long experience and knowledge of our affairs, is of great importance to us. I have now to introduce to you my successor in this chair.

A hearty vote of thanks was awarded to Dr. Rowand Anderson on the conclusion of the address.

## PYRAMIDS AND THEIR RELATION TO MONUMENTAL AND SACRED ARCHITECTURE.\*

(Concluded from last week.)

WE will now turn our attention to the second division of our subject—the relation of pyramids to sacred architecture.

The most striking adaptation of pyramids or structures of pyramidal form to the purpose of sacred architecture is to be found in Mexico and Central America. The conquest of Mexico by the Spaniards under Cortez in 1521 discovered to the Europeans a civilised people possessing considerable knowledge of the arts and sciences, having an architecture of their own, dwelling in cities protected by fortifications, and possessing a monarchical form of government with well-drilled armies, a system of religion with temples, priests and places of sacrifice, codes of morality and laws that would put to shame some of the civilised nations of the present time. The question as to the origin of this wonderful people has, I think, never been satisfactorily settled, nor is it a question for us to attempt to settle. A people commonly called Toltecs is said to have occupied between the fourth and sixth centuries of our era the valley of Mexico. The Mexicans do not pretend to any very remote antiquity or divine descent. There are no heroes who lived thousands or tens of thousands of years, nor any of the extravagances that usually mark the dawn of history in the Old World. On the contrary, their history modestly begins with the arrival of the Toltecs in Anahuac, and with them the beneficent teaching of a stranger who lived among them, taught them architecture and the arts of agriculture, instructed them in their religious duties, and then left them by sea promising to return. For three or four hundred years the Toltecs lived in peace, covering the tableland with their monuments. But evil times came. Famine, war and disaster drove them from their peaceful homes, and they migrated, it is said, southward toward Yucatan, where, it is usually assumed, they erected the architectural monuments whose ruins are now found in that country. From the departure of the Toltecs until the arrival of the Aztecs in the twelfth century nothing is known politically of the annals of Anahuac. The Aztecs were in peaceable occupation of the country at the time of its discovery and conquest by the Spaniards.

The principal monuments that these people have left behind them are the teocallis, literally "Houses of God," the temples of the people. These are pyramids in terraces with flat tops, and always surmounted by a chamber or cell, which is, in fact, the temple itself. They seem to be of all ages, for, if one may trust traditions, that of Cholula is as old as the early Toltecs, whereas the great teocalli of Mexico was only finished five years before the discovery of America by Columbus, and the Spaniards met with many persons who had assisted in its erection. It has, however, with all the native buildings of the city been swept away by the ruthless bigotry of the conquerors. Of these teocallis, the largest and probably the oldest is that of Cholula. Its dimensions are, so far as they can be ascertained in its present ruinous state, 1,440 feet square and 177 feet high, divided into four storeys, the fifth being formed by the cell or temple, which has now been replaced by a chapel dedicated to the Virgin Mary. There are two pyramids at Teotihuacan, the largest of which is a square of 645 feet, with a height of 171 feet, and there are others at Tezcucio of about the same size, and, like them, divided into five or seven storeys; but the most interesting of those brought to light is that of Xochicolo. It is situated on the top of what appears to be a natural elevation, but which has been fashioned into terraces by art. The pyramid itself is in five storeys. The stone facing of the three upper storeys has been removed to repair a sugar mill in quite recent time, but the two lower storeys still retain their sculptures and architectural ornaments. Besides the large many-storeyed pyramids there are numerous examples in many parts of the country of one storey only. Like all others in Mexico it is only a device to raise a temple to such a height as should give it dignity and enable the ceremonies performed on its upper platform to be seen by all the people. It is indispensably necessary to bear this distinction in mind in speaking of these monuments, as careless writers connecting the word pyramid with Egypt are too apt to confound two classes of monuments entirely distinct and dissimilar. The Egyptian pyramid is always a tomb. The principal object of its erection is the sepulchral chamber in its centre. It always terminates upwards to a point. In no instance are there external steps leading to a cell or chamber at the apex. In fact they were always tombs, never temples. The Assyrian pyramids, on the contrary, have much affinity with the building of which we are now speaking. They were always in terraces. The upper platform was always crowned with a chamber or cell, and there were external steps leading to this, which was the principal object of its erection. If we hesitate to admit that there was

any connection between the builders of the pyramids of Assyria and those of Mexico, we must at least allow that the likeness is startling and difficult to account for on the theory of mere accidental coincidence. It is quite probable that primitive man as he slowly emerged from the environments of ignorance with which his mental powers had been enshrouded, became convinced of an unseen and overruling power—a hidden mystery worthy of admiration. If such were the case the most natural objects of worship would be the objects by which he was surrounded. The sun being the most brilliant as well as the most potent object that met his gaze, would be one of the first to command his adoration. The moon and stars would in turn command his respect, and finally fire, as a representative of the sun, would become an object of worship. The same elements in nature, acting on minds in a similar condition, would produce similar results. The ancient Assyrian erected a pyramid, and on its flat top offered sacrifices to his god in the presence of the entire people. The more modern Mexican having by a similar process of mind reached a similar conclusion to that of the ancient Assyrian, proceeds in like manner to erect his pyramid, and upon its broad top to offer his sacrifices in the presence of the assembled multitude. We are informed that the Aztecs were most sincere in the practice of religious rites. They believed in a Supreme Creator, invisible yet omnipresent, but requiring numerous assistants to perform his will, each of whom presided over some special natural phenomenon or phase of human existence. They had thirteen principal and several hundred inferior deities. Their god of war was a patron divinity of the race, and myriads of human victims were sacrificed to him yearly. In each principal city there was the great pyramid, besides several smaller ones, and it is estimated that there were upwards of 40,000 of these places of worship in the empire.

The Toltec race, whose occupancy of the valley of Mexico preceded that of the Aztecs, is said to have emigrated southward and to have occupied what is now known as the peninsula of Yucatan. As in Mexico, the principal monument of Yucatan is the teocalli, but in this case their design is somewhat different from those in Mexico and they were probably erected for a different purpose. They are not generally in terraces like those of Mexico, but rise at about an angle of 45 deg., the platform on which the temple rests being reached by a broad flight of steps. The pyramid of Palenque, which is one of the most interesting ruins of Yucatan, may have been erected as a palace. The pyramid on which the superstructure is built is 310 feet long, 260 feet wide and about 40 feet high. The pyramid is divided into three parts by sill ribbons. The superstructure is reached by broad stairs on its west side. The buildings erected on the pyramid are one storey of 25 feet with flat roofs. Around three courts of different extent are grouped the corridors, halls and rooms. From the one of the five larger entries which extends the most outward, we reach by downward stairs of eleven steps the principal courtyard. Most remarkable are the ceilings of the rooms, formed by stone blocks joined one to another and the symmetrical square tower ending after many gradations in a steeple.

Stone sills bound by the perpendicular ribbons, which had friezes with pictorial work between them, divide the different storeys. All the masonry had an inward and outward covering of polished stucco ornamented with strange fantastical pictures. The floors are of stone, joined by cement and covered also with polished stucco. The other temples found in Yucatan differ but little from this one, except in size, and, architecturally speaking, they are less interesting than the palaces, the splendour of the temple consisting in the size of its pyramid, to which the superstructure is only the crowning member. In the palace, on the other hand, the pyramid is entirely subordinate to the building it supports, forming merely an appropriate and convenient pedestal, just sufficient to give it a proper degree of architectural effect.

Mexico, Central America and Peru each possess wonderful monuments of architectural skill. By whom they were wrought will probably never be known, as the nations who wrought them left behind no literature by which their identity or connection with the Old World can be established.

The final subdivision of my subject, "The Pyramidal Shaped Temples of India," will not occupy us for a great length of time. The earliest monuments of India are the rock-cut temples, which are of themselves so interesting that they will form the subject of a future paper. The structure of the earliest Indian temples was extremely simple. Pyramidal and of large dimensions they had no light except that which the door afforded. And indeed the gloom of the cavern seems to have led them to consider the solemn darkness of such a mansion sacred. There are ruins of this sort at Deogur and at a spot near Tanjore.

In proportion to the progress of the country in opulence and refinement their sacred buildings became highly ornamented, and must be considered as monuments exhibiting a high degree of civilisation of the people by whom they were erected.

Very highly-finished pagodas of great antiquity are found

\* A paper by Mr. Cyrus K. Porter in *Stone*.

in different parts of Hindostan, particularly in the southern part, where they were not subjected to the destructive fury of Mohammedan zeal. One of the most imposing structures of this kind is the pagoda of Chillamboram, near Porto Novo on the Coromandel coast. On account of its antiquity it is held in very great veneration. This monument should perhaps be more properly described as a cluster of pagodas enclosed in a space 1,332 feet in length and 936 feet in width, whose walls are 30 feet high and 7 feet thick, each side being provided with a highly-decorated frustum of a pyramid over the entrance gateway. The pyramids or pagodas which stand over the outer enclosures rise from rectangular bases and consist of several floors. The passage through them is level with the ground. One of the largest temples known is that on the small island of Seringham, on the Coromandel coast. It is situated about a mile from the western end of the island, and is thus described by Sonnerat:—"It is composed of seven square enclosures, one within the other. Each has four large gates with a high tower (pagoda), which are placed one in the middle of each side of the enclosure and opposite to the four cardinal points."

The outward wall is near four miles in circumference, and its gateway on the south is ornamented with pillars, several of which are simple stones 33 feet long and nearly 5 feet in diameter. Those which form the roof are still larger. In the innermost enclosures are the chapels. The extreme veneration in which Seringham is held arises from the belief that it contains the identical image of the god Vishnu which used to be worshipped by Brahma. The pagoda forms a very prominent feature in the architecture of Burmah. The one at Pegu is octagonal in plan, with a diameter at the base of 395 feet and a height of 361 feet. One on the Irrawaddy river opposite Ava is 944 feet in circumference and 160 feet high. The Burmese pagodas are usually square edifices of great extent, the base comprising porticoes and central chambers, and terminating upwards in octagonal or polygonal straight-lined pyramids. The pagoda also forms an important feature in the architecture of China. They are of brick covered with marble, or most generally with glazed tile, and are built in storeys one over the other from three, four or five to as many as nine in number. Each storey is reduced in width and has a gallery around it. The Chinese temples were frequently raised on a square pyramidal-shaped platform, and in this respect were similar to the temple or palace of Palenque in Yucatan.

Ever since the destruction of the world by the Flood there seems to have been a disposition among men of all nations to protect themselves from a similar occurrence by the erection of pyramidal towers, the first notable example of which was the Tower of Babel. The object for which this notable tower was erected having been by Divine Providence frustrated, mankind sought out new objects to which they could turn their attention.

The old kings of Egypt, wishing to hand down to posterity some evidence of their power and glory, erected immense tombs which have in all ages been the wonder of the world, in the centre of which they constructed a chamber insignificant in size when compared with the whole mass, in which a single sarcophagus was deposited, containing all that was left of their mortal remains. The ancient Assyrian and the more modern Toltec and his successor, the Aztec, inspired by religious zeal, erect for themselves immense pyramids with the tops truncated into a platform, upon which they can offer a sacrifice in adoration of the majesty of God as they understood him, or to appease his wrath when misfortune assailed them. The Hindoo, the Burmese and the Pagan Chinese beautified and adorned their temples with massive pagodas beneath whose shadows they offered their prayer, their offerings and their sacrifices to Brahma, to Vishnu, or to Siva.

Even the Christian Church has not been altogether exempt from this disposition to worship a Divine Being in places erected and dedicated to his service and ornamented by imposing towers and spires. As the Pagan Hindoo of old entered his temple through the ponderous pagoda that adorned its front, so do we of to-day enter our sanctuaries through towers beautifully designed, proportioned and ornamented, to chant hymns of praise and to worship the God of our salvation.

### THE PARTHENON IN 1830.

IN 1830 M. Raoul Rochette was sent by the French Government on an archaeological mission to Greece. The following report by him on the condition of the Parthenon and other buildings of the Acropolis is not without interest at a time when the restoration of the building is receiving attention:—

I must now speak of Athens, at least as far as I have seen, but here again the matter is so rich and so abundant that though I have only been at work for a fortnight I should have almost a volume to write. You are aware that the Acropolis was the sanctuary of ancient art as well as of the Athenian religion, and that it is there, notwithstanding all the revolutions and disasters which have afflicted and destroyed Athens, the

most beautiful monuments probably ever executed by mortal hand are still to be found. By a chance, which one can hardly admire enough, these monuments had scarcely suffered at all during the last war, in which the Acropolis served as the field of battle between the Greeks, who were in possession of it, and the Turks, whose batteries were erected in the neighbouring hills of the Museum and Pnyx. But since Athens has become the capital of Greece, the Acropolis has been made, in its turn, the particular object of the care of a Government which cannot be ignorant that the monuments and recollections of ancient Greece are among the first objects of interest which learned Europe associates with the destinies of the modern country. Their labours commenced with the removal of all the barbarous obstructions that encumbered the avenues of the Acropolis. The three Turkish batteries erected at different heights on the steps, and in the very bosom of the Propylæa, have been demolished; the walls which surrounded the columns of the façades of the Propylæa have been destroyed; in fact, it may be said that the ancient soil has everywhere triumphed over the barbarism which had possessed it, and now one may traverse without obstacle, and study without difficulty in all its details, the magnificent vestibule of the Acropolis, which ancient orators, in the utter want of words to express their admiration, could only compare to the Parthenon, and which they were pleased to associate with it with as much enthusiasm as if they had both been conceived by the same brain. But not only are the Propylæa at present free and without any foreign construction; still more has been achieved. In order to restore them as soon as possible to their primitive state much of the rubbish of the architectural elements of the Propylæa has been removed which had been employed as materials in the Turkish fortifications. Some of these elements have been already restored to their places; others which will be are lying on the ground, where they will be measured with greater facility and studied very closely, so that it is to be hoped that ere long the Propylæa will be reclaimed from that state to which they have been so long reduced. Among the most interesting appearances which have very recently resulted from this double work of demolishing and restoring, I must particularly notice the little Temple of Victory without wings, which had so long been a problem to antiquaries, as much as the Propylæa themselves, buried in Turkish buildings, had remained a mystery. This little temple is now found entire, with its four columns on both its façades, and with the walls of its cella on three of its sides. Each block of marble marked with the imprint of the time of Pericles has been brought from the middle of a mass of masonry and restored to its ancient place. The sculptures of the frieze have likewise been found; these had very happily escaped the hand of Lord Elgin, as they were hidden, like unhewn stones, in a modern wall—the only service the Turks could render to antiquity.

The Temple of Victory without wings will thus soon be re-established in all its integrity; all that is wanting are the four fragments of the frieze which are now in London; and England, which has reaped the fruits of Lord Elgin's operations, will certainly not refuse to restore to the Greeks the plaster in her possession, which would allow of the entire frieze being recomposed. I have had a drawing made with the greatest care of this precious monument of the time of Pericles, unexpectedly restored in our own. I have tried to do more, by asking from the king, for our museum, a model of the plasters of the basso-relievo recently found. His Majesty was pleased to inform me that it was his intention to offer a collection of them to the French Government; but architecture not being included in the projected mission, I have procured the Ionic capital, with its base; and it is a present which will, I am sure, be received with gratitude by our School of the Fine Arts, in which these precious remains of a Greek and Ionic Order so pure and elegant will so justly take their place in our gallery of architecture. I will likewise procure models of the capital and base of the Ionic Order of the interior portico of the Propylæa, which are in all respects most interesting remains of the history of ancient art, restored almost intact by the last excavations. In fact, in order to complete this series of examples, all of the highest class, imprinted on the finest monuments of Grecian antiquity, it is also my intention to get models of two of the Ionic capitals of the Erechtheion, a double temple with a double portico, a veritable wonder of ancient art, in the composition of which there are three different Ionic Orders, of which I believe we only possess one specimen in our architectural gallery.

In the state in which the Propylæa are at present, with the Temple of Victory without wings in front of the left wing, and the Pinacothèque, which forms the right wing, and only wants the ceiling, and of which the four admirably fitted walls have been found intact, I have been able to show as a whole and in details this superb vestibule of the Acropolis in a manner which I have no hesitation in saying will surpass all the works from the time of Stuart to our own.

As soon as we have completed our labours on the Propylæa

M. Morey and myself intend to undertake an examination of the Erechtheion, which is now almost wholly freed, and, consequently, in a state in which it could not have been seen by any of the antiquaries and architects who have preceded us. But by means of what has been already restored to its place, and what is lying on the ground, a more correct and complete architectural study of the Erechtheion may be now made than has ever yet been effected; and this result of my voyage, were it the only one, executed with all the care and talent M. Morey could and has bestowed on it, will certainly be of great interest to science.

The Parthenon has also, of late years, occupied the cares of the Greek Government, but unhappily without its being in the power of this Government, or any one in the world, to repair the frightful losses this monument has suffered, and of which you, as well as the whole of Europe, are aware; the most cruel, and still the most sensible, are not those which it owes to the cannons of the Venetian or the barbarity of the Turks. The mosque erected in a part of the *cella* of the Parthenon will soon disappear, but the sculptures removed from the pediment and frieze by Lord Elgin will never come back; and here is a frightful void, which is everywhere felt, and more so at Athens than elsewhere.

In order to repair as much as possible the losses sustained in this manner, excavations are being made in the masses of rubbish which still cover the soil and avenues of the Parthenon, and four fragments of the frieze, probably the most beautiful in existence, have happily been found, and, though long buried in the ruins of the edifice, they have not suffered from attacks of age or barbarism. These fragments are really *chefs-d'œuvre*, all four being of different subject and character. I have made careful drawings of them, and have obtained King Otho's promise that plasters of these admirable basso-relievos should be offered to the French Government, and sent to Paris at the same time as those of the frieze of the Temple of Victory. Paris will thus soon have fresh means of appreciating the art and taste of Phidias from some of the most beautiful fragments of his chisel; and if this lesson is not lost, like many others, it ought to profit France as much as it will honour Greece. I should not forget to state that in an excavation opened last year at the south-east angle of the principle façade of the Parthenon, numerous fragments of the ancient Temple of Minerva, burnt by the Persians, have been found at a depth of about 12 feet; they were undoubtedly buried by the Greeks themselves, as materials of no value, when they constructed the Parthenon under the administration of Pericles. But these fragments, nothing to ancient Greece, are at the present time precious remains of the history of art; they consist of tiles, called *antefixa*, of fragments of cornice and frieze, of burnt-coloured earth, which are authentic monuments of a taste for polychrome architecture; an archaeological question of the greatest interest to artists and antiquaries. I have made drawings of all these fragments, with their colours exactly marked; and it is the first fruit of my researches in Greece that I expect on my return to publish remarks, as those which will most directly benefit science, on one of the questions which is most before the archaeological public.

#### THE TOUR DE L'ÎLE, GENEVA.

THE following communication from Mr. Lawrence Harvey, architect, appears in the *Geneva Telegraph*:—

On the island which divides the Rhone into two channels there is a very old tower. It is a very ugly tower which few of the visitors to Geneva even notice. On account of its plainness there is some likelihood of its being pulled down, to the grief of lovers of antiquity who are agitating for its being left standing.

This tower is the remnant of an old castle built in 1219 by a bishop of Geneva in order to protect himself against neighbouring feudal chiefs, called the Counts of Genevois. From that time this venerable relic has been the witness and often the centre of every memorable event that has happened in Geneva.

The power of the Counts of Genevois waned and was replaced by that of the House of Savoy, the same which now rules over Italy. The island castle, defended by two of the canons of the cathedral and a few Geneva citizens, was besieged and taken by the Counts of Savoy. From the stronghold of liberty under the good bishops of Geneva, it became the stronghold of tyranny. The bishops became the mere tools of the family of Savoy, the noblest sons of Geneva suffered martyrdom within the walls of the very tower which still remains, and at last the excess of evil brought on the Reformation, that great religious and likewise political revolution which has changed the course of the world.

It is not unlikely that if the last bishop of Geneva had been faithful to his trust as sovereign and guardian of the Geneva State there would have been no religious change in Geneva, no Calvin, no Knox, no Bishop Miles Coverdale, and consequently

no Oliver Cromwell and no Jean Jacques Rousseau. Neither would there have been a free Holland, nor a learned Scotland, nor a go-ahead Massachusetts and afterwards United States of America, for all these were leavened by the spirit of John Calvin. Nor would there have been a French revolution to realise the contract social which Jean Jacques Rousseau had discovered from the example of his native city.

But this is not all. The old tower stands close to the spot where Julius Cæsar, the greatest man of antiquity, started to discover Gaul and Great Britain fifty-eight years before the Christian era, a fact equal in importance to the discovery of America by Christopher Columbus. Yet this tower, hallowed by such world moving memories, bears not a single inscription to record the fact, and it is now contemplated by the Geneva authorities to remove the tower altogether. At all events, not the slightest effort has been made to keep the tower. A huge building is being erected close up by which the tower will be dwarfed and made more unsightly than it was; and yet it would have been so easy to have erected a building equally useful for practical purposes which would have included the tower in its design. To obtain this result it would have sufficed to bind the buyer of the land to the condition of erecting a building in which the tower would have been included to the satisfaction of the Town Council. Nothing was done, and we may conclude that nothing was wished to be done.

Such want of appreciation of old landmarks of history can only be explained by the fact that the Genevese people have practically disappeared to make room, as an American city, for a floating population come from all parts of the earth. It is a fact over which Englishmen, the old and staunch friends of Geneva, may mourn but cannot help. *Sic transit gloria mundi*.

#### TESSERÆ.

##### Philibert Delorme on Compliant Architects.

NOTHING strikes us as worse and more ridiculous than to wish, as happens only too frequently nowadays, to impose on architects something else than programmes; nothing gives a more gloomy idea of the state of the arts and those who profess them than to see artists accept all the extravagancies imposed by persons ignorant of practice under the pretext that they pay the bills. Tailors have on this score more moral courage than many architects, for a good tailor will say, if one orders a ridiculous coat, "I cannot make you a garment which will disgrace my house, and which will make a laughing-stock of you." This evil dates sufficiently far back, for Philibert Delorme wrote about 1575:—"I desire to inform you that for thirty-five years gone and more I have observed in diverse places that the major part of those who have made or desire to make edifices have begun them even so hastily as they have lightly considered of them; thereby has resulted most often repentance and derision which always follows those ill-advised in such wise that they who think to understand truly that which they would do have required the contrary of that which was possible and ought indeed to be done. And if by good chance they sought from someone advice touching their resolve and undertaking, it was a master-mason or master-carpenter, as one is wont to do, or perhaps some painter, some notary, or others who hold themselves for well informed, and for the generality have hardly better judgment and counsel than those who ask it from them. Oftentimes likewise I have seen great personages who have decided themselves, for as much as the most part of those who are about them, never wishing to gainsay them or desiring to please them, or, indeed, because they themselves lack understanding answer straightway with the words, 'It is well said, my lord; it is a fine invention; it is very well imagined, and shows truly that you have an excellent understanding; never will such another work be seen in the world.' But the flatterers think quite otherwise, and talk of it behind his back, or perhaps elsewhere. In this wise many seigneurs cheat themselves, and are satisfied with their achievements."

##### St. Mary's Abbey, York.

The early history of this abbey appears to be lost in obscurity; it is, however, almost certain that there was a monastery on the site during the time of the Saxons. Coming down to the Norman era, we have a very clear and precise account by Stephen, called the first abbot. He can only have been the first abbot of the new monastery which was built by him, as Roger de Hoveden (Howden) says, "In the year 1056 Leward, the brave earl of the Northumbrians, died, and was buried in the cloister of the monastery of St. Mary without the walls." The first stone of a new and much larger establishment, over which Stephen ruled, was laid by William Rufus when he visited York, soon after his father's death. Stephen died in 1112. Stow mentions that during the time of Savaracus, the fourth abbot, the monastery was burnt in a dreadful conflagration; but it must only have been partial, for there is

no record of rebuilding from the time of Stephen until that of Simon de Warwick, elected abbot in 1258, who appears to have raised the state of the monastery to one of great splendour and security. From the time of Simon until the dissolution the records are lost, and we have only the mere names of the eight remaining abbots. The remains, however, bespeak an almost entire rebuilding about the year 1450, when William Wells was abbot, he having been elected in 1423, and resigned in 1456, being appointed to the see of Rochester. Taking the epochs of the rebuilding of the different parts of the monastery from the remains, they divide themselves into five distinct periods:—First, the Saxon, of which the only remains are the rough foundations of the east end of the church; second, the Norman, when the monastery was entirely rebuilt by Stephen, under the auspices of William Rufus, about 1100—the remains are the great gateway from Marygate, the vestibule to the chapter-house (exceedingly beautiful as to plan and details), the misericord, the cellarer's office, the school of the monks, and the rough foundations of the north-east part of the east end of the church; third, the Early English, when the church and chapter-house were entirely rebuilt by Simon de Warwick, from 1250 to 1290, of which there are extensive remains; as also of the fourth, the enriched Gothic, about 1450; fifth, the works that appear to have been going on during the time of the dissolution. The walls of a chamber of this period over the gateway are lined with brick; there is no appearance of this material being used before. From the comparative value of the northern abbeys and priories, as given in Dugdale's "Monasticon" by Stephens, the abbey of St. Mary's, York, was considerably the richest.

#### Classification of Crystals.

The primary forms of crystals are arranged in systems, each system containing those forms which have an equality in the number, size and direction of the axes. Six systems are admitted, namely, the cubic or tessular system, having three perpendicular equal axes; the right square prismatic system having three perpendicular axes, two only of which are equal; the rhombohedral system having four axes, three equal and inclined to each other at an angle of 60 deg., the fourth unequal and perpendicular to the other three; the right rhombic prismatic system, with three perpendicular unequal axes; the oblique rhombic prismatic system having three unequal axes, one oblique on the second but perpendicular to the third, the second and third being mutually perpendicular; lastly, the doubly oblique prismatic system having three unequal axes, all mutually oblique. Now, it is remarkable that certain optical and other properties are connected with these systems. Thus, the crystals of the cubic system possess the power of simple refraction only, and when heated expand equally in all directions. The crystals of all the other systems enjoy the property of double refraction and expand unequally in certain directions when heated, but in all doubly refracting crystals there is one or more directions in which no double refraction takes place: these are called the axes of double refraction. The crystals of the right prismatic and rhombohedral systems have only one axis of double refraction, while those of the right rhombic prismatic, oblique rhombic prismatic and doubly oblique prismatic system have two axes of double refraction. In some doubly refracting crystals the extraordinary ray is refracted from the axis; in others, towards the axis. The first are called negative or repulsive, the second positive or attractive. Now, it is remarkable that those crystals which have a negative or repulsive axis expand, when heated, most in the direction of their axis; while those with a positive or attractive axis expand the least in that direction. These facts show that while the elasticity of crystals of the cubic or tessular system is equal in three rectangular directions, it varies in different directions in all other crystals. In those of the right prismatic system it is equal in two perpendicular directions; in those of the rhombohedral system it is equal in three directions, which are mutually inclined at an angle of 60 deg. In the three remaining systems it is unequal in three different directions. As the properties of crystals are considered to be those of their constituent molecules, it follows that the forces which act in the crystal must act in the constituent parts.

#### Sir Joshua Reynolds.

Reynolds was really a great artist; gorgeous in tone and colour, unimpeachable in composition, deep in light and shadow, beautiful in character, and the purest painter of children and women that ever lived in the art, Greek or Italian. His ignorance belonged to the period, his beauties were entirely his own; and, though he overrated Michel Angelo, and has done injury to taste by his sincere conviction that he was right, yet, had he lived to see the Theseus or Ilyssus, he would have been equally candid in saying he was in error. Lord Heathfield is a portrait that need not fear any work of Titian's for men, and Mrs. Parker, a tender, sweet picture of a woman, was never equalled in sentiment or delicacy by any work of the Venetian and Roman schools. Where were children ever so completely

hit as in the *Infant Academy*? Who surpassed the propriety of his backgrounds as well as their splendour? His eye, or rather his organ for colour, was exquisite, nor is there in the whole of his works a heated and offensive tint. He did not combine essential detail and breadth so beautifully as Titian; but place one of his finest portraits by the side of any picture of Titian's, see them at the proper distance, and Reynolds would keep his station. Here, however, the praise must stop. Reynolds could have no more painted *Pietro Martire* than he could have revived the martyr after he was dead. He was not so great a man as Titian, because he did not, like him, remedy his ignorance when he found it out at a much earlier age. He was always talking of what he would do if he began the world again. Sir Joshua loved society; he was the deity of his coterie; he liked a glass of wine and a game at whist; and he never lost his temper—because he was successful in the world, but the first time he was thwarted he got in a passion. Reynolds was a great genius in painting, but not a great man. He raised English art from the dust, and gave English artists an *aplomb* in society which they never had before, and he first reduced the art to something like system by his discourses; but not having moral courage to resist the formation of an academy, which he could have done by his influence and his genius, he compromised the art and was indirectly the means of throwing it off its balance.

#### The Nimbus in Christian Art.

The nimbus was originally given in Christian art to sovereigns and allegoric personages generally as the symbol of power or distinction, but with this difference, that round the heads of saintly and orthodox kings or emperors it is luminous or gilded, round those of Gentile potentates it is coloured red, green, or blue. About the middle of the third century it begins to appear, and at first as a special attribute of Christ, later on appearing round heads of angels, evangelists and apostles. Finally, it was assigned to the Blessed Virgin and all saints, but not as their invariable attribute before the seventh century.

#### GENERAL.

**The Duke of Norfolk**, Mayor of Sheffield, has given a plot of ground of 20 acres in the Brightside division for use as a public park, in commemoration of the Diamond Jubilee and the Queen's visit to Sheffield.

**The Comtesse de Castellane**, née Gould, has given 1,000,000 francs for the purchase of a plot of ground and the construction thereon of a safe, durable and commodious building for the annual charity *fêtes* in Paris. The Cardinal Archbishop of Paris intends to purchase, if possible, the land in the Rue Jean-Goujon in order to found some charitable work.

**The French Government** have presented to the Académie the painting by M. André Brouillet which represents the reception of the Emperor and Empress of Russia by the Academicians on October 7, 1896.

**The Slade Professor of Fine Art**, Mr. H. E. Wooldridge, M.A., will give his first three lectures upon the "Sphere of Paduan Influence" on Monday, Tuesday and Wednesday, May 24, 25 and 26, at the University Galleries, Oxford, at 4 P.M.

**The Awards** to British artists at the Dresden exhibition are as follows:—*Large Gold Medal*—Mr. Strang. *Small Gold Medals*—Mr. Watson, Mr. La Thangue, Mr. Roche, Mr. Cameron, Mr. Pegram and Mr. Frampton.

**The New Garrison Church** at Strassburg, which was commenced in April 1892, has cost 1,400,000 marks. The architect is Herr Louis Müller, of Frankfort. The style adopted is local Gothic, and the building will accommodate 3,000 worshippers.

**Messrs. Layton**, the insurance publishers, have arranged with Mr. Edwin O. Sachs for the immediate publication of a treatise entitled "Fires and Public Entertainments," which will include exhaustive particulars of over 1,200 fires which have occurred at theatres, music-halls, assembly-rooms and temporary buildings, involving over 20,000 fatalities. Mr. Sachs's collection, with its analysis, has been in preparation some considerable time; and he aims at strengthening the hands of those anxious to insure the safety of the public when attending places of amusement.

**Mr. Dodgshun**, of Leeds, is preparing plans showing new receiving wards and new tramp wards in order to extend the Hunslet Workhouse so as to give more room for the old men, and to provide a larger kitchen and new bath-rooms, school building, hospital with accommodation for nurses, &c.

**The New Swing Bridge** over the Dee at Queensferry, Hawarden, is rapidly approaching completion, and it is expected that it will be ready for opening by Mr. Gladstone on Whit-Monday.

# The Architect.

## THE WEEK.

THE award of the medals in the Architectural Section of the Salon gave rise on Friday last to some commotion. For the Médaille d'Honneur M. PONTREMOLI obtained 37 votes, M. MARCEL 32, M. CHANCEL 9, MM. MARCEL and BLANC 2, M. BLANC 1. As by the regulations at least 42 votes were required, it was necessary to make a second attempt, when M. MARCEL gained 43, M. PONTREMOLI 39, MM. MARCEL and BLANC 3. This attempt also was fruitless, for 44 votes were necessary. M. GINAIN, who served as president, accordingly declared that the Médaille d'Honneur would not be awarded. But the electors protested, declaring that as M. MARCEL had obtained 43 votes on his account, and with his partner shared in 3 votes, he had complied with the regulations. M. GINAIN was not to be moved, and accordingly the voters sent a demand to the committee for another trial. The other medals were awarded as follows:—1st class medal: M. PONTREMOLI. 2nd class: MM. EUSTACHE, MORIN-GOUSTIAUX, BLANC, MAISTRASSE and BERGER. 3rd class: MM. TONY GARNIER, WOOG, PAILHES, GUILLAUME, CHAUSSEPIED, HÉBERARD, LE GRAND and DEMIERRE. Honourable Mention: MM. BOURBIER, CARRÉ, CHESNAY, DEMUR, EICHMULLER, GUYOT & POTTIER, HERVEY-PICARD, JASSON, LEGRESLE, MESNAGER, OLIVIER, ROME. For painting, M. HARPIGNIES, the landscapist, has obtained the Médaille d'Honneur; in sculpture, M. MATHURIN MOREAU has been successful; and in engraving and lithography, the Médaille d'Honneur was awarded to M. SIROUY, whose masterpieces, *Athalie* and *Arcadia*, were reproduced in *The Architect*.

DURING several years Mr. C. J. PHIPPS, who died suddenly on Tuesday morning in his sixty-second year, could claim a monopoly in the erection of theatres. So strong was his hold on managers, it was one of the legends among theatrical people that whenever an announcement appeared of the burning or condemnation of a theatre a bottle of champagne was at once opened in Mr. PHIPPS's office, to drink prosperity to the new building. He could safely assume the commission for it was to come to him without delay. That the style he employed was generally commonplace was an advantage in the eyes of lessees, for in a speculation of the kind economy was to be studied. It was well known that playgoers cared little about the exterior of a theatre, and colour and gilding could compensate for defects of form in the interior. Mr. PHIPPS was supposed to make sacrifices of his art in the interests of his clients, and he could not have a better recommendation. At length there was a change, and he was forced to see the designs of younger men accepted in preference to his own, and buildings raised which were in keeping with the times, although capacious and economical. While he enjoyed favour Mr. PHIPPS was the architect for about seventy theatres, a number exceeding all experience of one man's work. Moreover, he was the patentee for seats and other appliances, so that a new theatre brought him profit in more ways than one. But numerous as are his buildings, his fame will hardly be more enduring than that of the men and women who performed on his stages. His latest metropolitan theatre is the new Her Majesty's in the Haymarket, which shows a departure from his customary type, which he first created in Bath. It is supposed that Mr. PHIPPS caught a chill while returning on Saturday from a building at Dover, and as he had been lately in delicate health, he succumbed with an ease which was not anticipated. His practice will be continued at 26 Mecklenburgh Square, W.C., by Mr. ARTHUR BLOMFIELD JACKSON, who was associated with Mr. PHIPPS as partner in his more recent works.

We have often pointed out the necessity for a commission to apportion catchment basins for water-supply, in order to prevent "grabbing" by one town at the expense of another. No less important would be arrangements con-

cerning underground water. According to Mr. BALFOUR BROWNE, Q.C., "the law of underground water as it now stands is simply silly." At the Engineering Conference on Tuesday, Mr. JAMES MANSENGH referred to the recent contest between the Corporations of Newark and Nottingham on the subject. Both had obtained their water-supply from wells sunk into the pebble beds of the new red sandstone. The Nottingham Corporation recently attempted to extend their district with the intention of sinking wells. The Newark Corporation, in self-defence, proposed a Bill to secure a protective zone of four miles radius. Mr. MANSENGH considered that in the case of surface streams the law was clear, righteous and intelligible—that a man must allow the water flowing over his land to pass on to his neighbour, having only a fair and reasonable use of it in its passage through his land. Having glanced at the geological question as to the outlet into the sea from the pebble bed, and at the question of the amount of percolation into the pebble beds in terms of the rainfall, Mr. MANSENGH urged that something ought to be done to simplify and put on a sensible basis the allocation of underground water-bearing areas. The difficulty will be to convince a parliamentary committee that sufficient knowledge is attainable to allow of justice to all sides in parcelling out underground water-beds.

It is satisfactory to find that no deaths occurred during the execution of the Blackwall Tunnel. But as caissons are adopted in America for laying the foundations of buildings and may also be introduced in England, it is well to know there is a special compressed air illness or caisson disease which often ends fatally. That the men who toiled beneath the Thames did not succumb must be attributed to the precautions taken by the contractors in order to minimise the danger of the system. Dr. SNELL, the resident medical officer at the tunnel, and who was always at his post, has notes of 200 cases of illness arising from compressed air, and he believes many more were not brought under his notice. Several men were so severely affected they declined to continue on the works. Even robust men writhed with the excruciating pains for weeks or months. The impurities in the air are one source of danger. How much depends on care was exemplified at the bridge over the Mississippi at St. Louis. During the sinking of the first pier twelve lives were sacrificed, but at the second pier under similar conditions only one man died. It is astonishing how easily the air can become dangerous. Charges of tonite which were fired to ease one of the compartments of the shield at Blackwall increased the quantity of carbonic acid above the safe limit; at another time the increase was owing to the works being then under what had been the Isle of Dogs sewer, and it is also supposed the lime used for grouting in the tunnel making lime-water was a cause. When the carbonic acid exceeded 1-1000 additional air was pumped in, but in such a place that air could not always be considered as absolutely pure.

It is unusual for a parliamentary committee to issue a sort of emergency report, but in the case of the South Kensington Museum that course is praiseworthy. Already several artists have approached Sir JOHN GORST recommending the immediate completion of the buildings, but the Paris catastrophe having given an overwhelming proof of the expedition with which temporary buildings can be consumed, we now have Sir JOHN GORST and his committee as eager as any artists or visitors for the commencement of the works. We print the report on another page, and the array of dangers described is enough to scare any fireman. Old lath-and-plaster buildings, varnished matchboarding, wood lanterns, skylights, open sidelights, canvas lining to walls, tarred felt, wood partitions, flimsy construction are among the sources of danger. In the "residences" are eighty-one open fire-places, and a domestic accident might at any moment be the beginning of a conflagration. When it is remembered that the collections which have been so long imperilled are of more importance than those in any other museum, the urgency of an immediate starting of the indispensable works cannot be denied.

### SIR WALTER SCOTT AS AN ARCHÆOLOGIST.

THE fixing of a bust of Sir WALTER SCOTT in Westminster Abbey, which was unveiled on Saturday last, was one of those events, like the hall-marking of gold or the presentation at Court, which are supposed to determine for ever the character of the subject. To the world in general SCOTT will not be any higher than he was last year, but a certain class of people will feel that they can consider him henceforth as more deserving of their approbation. We may therefore be allowed to use the occasion as an opportunity to consider some aspects of his genius to which the majority of his readers are indifferent.

There may have been greater writers of romances and greater novelists, but in his power to produce both classes of blessings to mankind SCOTT was unique. He knew the limits of each. Romance, according to him, was "a fictitious narrative in prose or verse, the interest of which turns upon marvellous and uncommon incidents," and generally relating to an age which has passed, while the novel was "a fictitious narrative differing from the romance because the events are accommodated to the ordinary train of human events and the modern state of society." SCOTT was a shrewd observer, and among his contemporaries there was not one who was better acquainted with life in Edinburgh, and in the region which is associated with him in Selkirk and Roxburgh. But he gained his power by raids into the past. Starting with "sixty years since," he entered periods more remote, and he appeared to exercise as much power over the beings of the eleventh century as over the Highlanders who had made a final struggle to restore the STUARTS. Whether it was due to second sight, imagination, scholarship, or a combination of the three is not easily decided, but the power was a gift which professed historians vainly coveted. AUGUSTIN THIERRY declared there was more real history in SCOTT's novels than in the philosophical but false compilations betitled histories, for "everything peculiar to the time and place, the exterior of men, the aspect of the country and of the habitations, costumes and manners are described with the most minute truthfulness, and yet the immense erudition which has furnished so many details is nowhere perceived." CARLYLE also insisted on the minute truthfulness with which the vanished races were restored to life:—"There they were, the rugged old fighting men, in their doughty simplicity and strength, with their heartiness, their healthiness, their stout self-help, in their iron basnets, leather jerkins, jack-boots, in their quaintness of manner and costume; there as they looked and lived; it was like a new discovered continent in literature." The truthfulness of SCOTT in describing habitations, costumes, manners, &c., was not so wonderful as is commonly supposed. His books are not manuals of archæology, although they have done more to resuscitate the past than all the manuals which have appeared in all languages. SCOTT was too versed in business to be ignorant of the fact that readers of romances will only take archæology in homœopathic doses, and, however small, they must be disguised, or the book will be set aside. The advice he once offered to authors reveals his own method:—

He that would please the modern world, yet present the exact impression of a tale of the Middle Ages, will repeatedly find that he will be obliged, in despite of his utmost exertions, to sacrifice the last to the first object, and eternally expose himself to the just censure of the rigid antiquary, because he must, to interest the readers of the present time, invest his characters with language and sentiments unknown to the period assigned to his story; and thus his utmost efforts only attain a sort of composition between the true and the fictitious—just as the dress of Lear, as performed on the stage, is neither that of a modern sovereign nor the cerulean painting and bearhide with which the Britons, at the time when that monarch is supposed to have lived, tattooed their persons and sheltered themselves from cold. All this inconsistency is avoided by adopting the style of our grandfathers and great-grandfathers, sufficiently antiquated to accord with the antiquated character of the narrative, yet copious enough to express all that is necessary to its interest, and to supply that deficiency of colouring which the more ancient times do not afford.

The recipe may appear easy, but SCOTT did not find it so. CARLYLE considered he was only an improviser, but the preparation for the feat involved enormous labour. When SCOTT was recommended in his last days to allow his wearied brain some repose, he said it was like the servant bidding the kettle on the fire not to boil. He could

not help thinking, and for a great part of his life his thinking was about remote times. SCOTT was lame, and on that account might be supposed to divide his life between his office and his library. But he loved action, for it enabled him to give more reality to his peculiar thoughts, which were rarely far removed from "feats of broil and battle," or manly exercises which were a fitting preparation for a soldier's life. There is a story related by HOGG, the Ettrick Shepherd, which enables us to see the difference between WALTER SCOTT and most of the poet archæologists, for he never cared to see his face in a looking-glass "sicklied o'er with the pale cast of thought":—

I remember his riding upon a terribly high-spirited horse, which had the perilous fancy of leaping every drain, rivulet and ditch that came in our way; the consequence was that he was everlastingly bogging himself, while sometimes the rider kept his seat despite of the animal's plunging, and at other times he was obliged to extricate himself the best way he could. In coming through a place called the Milsey Bog I said to him, "Mr. Scott, that's the maddest de'il of a beast I ever saw. Can ye no gar him tak a wee mair time? He's just out o' ae lair intil another wi' ye." "Ay," said he, "he and I have been very often, these two days past, like the Pechs; we could stand straight up and tie our shoe-lachets." I did not understand the joke, nor do I yet; but I think these were his words. We visited the old castles of Thirlestane and Tushilaw, and dined and spent the afternoon and the night with Mr. Brydon of Crosslee. Sir Walter was all the while in the highest good-humour, and seemed to enjoy the range of mountain solitude which we traversed exceedingly. Indeed, I never saw him otherwise in the fields. On the rugged mountains, or even toiling in the Tweed to the waist, I have seen his glee not only surpass his own, but that of all other men. His memory, or perhaps I should say his recollection, surpasses that of all men whom I ever knew. I saw a pleasant instance of it recorded lately regarding Campbell's "Pleasures of Hope"; but I think I can relate a more extraordinary one. He and Skene of Rubislaw and I were out one night, about midnight, leistering kippers in Tweed, and, on going to kindle a light at the Elibank March, we found, to our inexpressible grief, that our coal had gone out. To think of giving up our sport was out of the question; so we had no other shift save to send Rob Fletcher home, all the way through the darkness, the distance of two miles, for another fiery peat. While Fletcher was absent we three sat down on a piece of beautiful greensward on the brink of the river, and Scott desired me to sing him my ballad of "Gilmanscleuch." Now, be it remembered that this ballad had never been either printed or penned. I had merely composed it by rote; and, on finishing it three years before, I had sung it once over to Sir Walter. I began it at his request, but at the eighth or ninth verse I stuck in it, and could not get on with another line; on which he began it a second time, and recited it every word from beginning to end. It being a very long ballad, consisting of eighty-eight stanzas, I testified my astonishment. He said that he had lately been out on a pleasure party on the Forth, and that to amuse the company he had recited both that ballad and one of Southey's ("The Abbot of Aberbrothock"), both of which ballads he had only heard once from their respective authors; and he believed he had recited them both without misplacing a word. Rob Fletcher came at last, and old Laidlaw, of the Peel, with him, and into the foaming river we plunged, in our frail bark, with a fine blazing light. In a few minutes we came into Gliddy's Weal, the deepest pool in Tweed, when we perceived that our boat gave evident symptoms of sinking. When Scott saw the terror that Peel was in he laughed till the tears blinded his eyes. Always the more mischief the better sport for him. "For God's sake push her to the side!" roared Peel. "Oh, she goes fine!" said Scott; "an' gin the boat were bottomless, an' seven miles to row;" and by the time he had well got out the words, down she went to the bottom, plunging us all into Tweed over head and ears. It was no sport to me at all, but that was a glorious night to Sir Walter—and the next day was no worse.

In this picture we see SCOTT projecting himself, as it were, into the past and leading the life of one of his moss-trooping ancestors. But he does not forget to visit old castles as if he were on a special archæological excursion, and the period of accidental repose is turned to account in the recitation of heroic ballads, just as the borderers would have done after a successful foray before the Last Minstrel had appeared at Newark's stately tower. What better preparation could be found for a man who wished to describe ancient life in Scotland? About his manner of studying buildings SCOTT furnishes some delightful lines:—

Crichton! though now thy miry court  
But pens the lazy steer and sheep,  
Thy turrets rude, and totter'd keep,  
Have been the minstrel's loved resort.  
Oft have I traced within thy fort  
Of mouldering shields the mystic sense,  
'Scutcheons of honour, or pretence  
Quarter'd in old armorial sort,  
Remains of rude magnificence.

The extent of SCOTT's erudition is evident from the number of books which he refers to in his writing. He was not perhaps a dry-as-dust student, for his nature compelled

him to enter heartily into whatever he undertook ; but he was able to seize the character of all the volumes to which he referred and he employs them for his own purposes like a true scholar. It is no wonder then that when describing buildings, and especially what might be called baronial residences, SCOTT uses words which excite the imagination, but which afterwards cause some disappointment to strangers when they see some of the dwellings of Scottish chiefs for the first time. His glowing fancy and his patriotism made ancient buildings appear sublime, and he compelled not only the English people, but those in all countries who were reached by translations of his works, to consider Scotland as a sort of architectural paradise, and Northern Gothic as a style which surpassed the Grecian. SCOTT, we may be sure, was able to take an exact view of the peculiarities which belonged to Gothic. With him it was the mason rather than the cut stone which absorbed his attention. It seemed absurd to him that a man like HORACE WALPOLE should suppose it was possible to create a Gothic mansion because the chimneypieces, ceilings, windows and balustrades were made out of fragments collected from cathedrals and monuments, although SCOTT himself, under the pressure of a desire to see Abbotsford quickly completed, abstracted many carvings from Melrose. He wished to have evidence of individuality in buildings. On that account he preferred to see a castle uninhabitable, although the walls were entire, rather than have a restoration which would destroy its character as a memorial of antiquity. With him restoration signified timely and reverential attention, by which not only actual destruction but the slow progress of decay was arrested.

The conflict in SCOTT's mind between the archaeologist and the modern citizen was curiously exemplified in what he said about Edinburgh houses. He was like PLEYDELL in "Guy Mannering," and considered there was no view equal to what could be seen from an upper window in an old-fashioned house. But his love of the picturesque, however, could not make him close his eyes to the deficiencies of the flats in his own romantic town. Sickness, he said, had in them no nook of quiet, affliction no retreat for solitary indulgence, many of the rooms were dark even at noon-day, or borrowed but a gleam from some dark alley. On the other hand, he could say on behalf of them that in an Edinburgh *land* a sort of general interest united the whole of the inhabitants from the top to the bottom of these lofty tenements.

SCOTT, it should be remembered, was a born aristocrat, and although as an author, printer and publisher—for he combined the three callings in the hope of making more money—he wished to make all classes fascinated with romance, if he had the power he would have restricted the use of buildings that recalled feudal manners to nobles or to gentlemen like himself. If need be let plebeians suffer in preference in the lofty and dark mansions of the Old Town. Writing in 1821, when his poems and the series of novels from "Waverley" to "Ivanhoe" had produced their effect in compelling many people to surround themselves with imitations of Mediævalism, SCOTT said, with more of contempt than of pity :—"The Gothic order of architecture is now so generally and, indeed, indiscriminately used, that we are rather surprised if the country-house of a tradesman retired from business does not exhibit lanceolated windows, divided by stone shafts and garnished by painted glass, a cupboard in the form of a cathedral stall, and a pig-house with a front borrowed from the façade of an ancient chapel." The mock Gothic of that time was defective ; indeed some critics consider that the most perfect imitation of Gothic must be an anachronism in the nineteenth century, but the last man to deride it should have been WALTER SCOTT.

Strange as it may appear, SCOTT's aversion to Gothic houses was, we believe, not so much on account of the style as the comfort which was at the disposal of people who could make no claim to be considered gentry. That at least is the conclusion we draw from what he said about the New Town of Edinburgh. In the old days, when people lived in flats and from want of space were obliged to meet in the assembly-rooms on festive occasions, then it happened, says SCOTT, that "all persons of rank and fashion entitling them to frequent such places met upon easy and upon equal terms, and without any intrusion on the part of others," and "the pretensions of everyone were known and

judged by their birth and manners, and not by assumed airs of extravagance or a lavish display of wealth." FERGUS MACIVOR could hardly assume a more lofty tone if he had to speak of the modern race of citizens. The upstarts who possessed all qualities but birth were, however, moral in their conduct, or at least they were not found out. SCOTT is forced to admit that fact, although they had abandoned flats which their fathers contentedly occupied, and descended from their "common stairs" to claim the dignity of a front door. "In the present condition of Edinburgh," he says, "the men have gained much on the score of sobriety, while the women have, *as yet*, lost none of that high character for conjugal, filial and maternal affection for which they have been long distinguished. An 'arrangement,' so common in the London circles, is a word unknown ; and since scandal is silent we may safely conclude that little cause exists for calumny." Could love for the past go further? SCOTT admired his countrymen and countrywomen, but because they found it was more advantageous to live in dwellings which were not crowded like rabbit warrens, he became apprehensive that the more healthful living must cause them to succumb to temptation. Modern sanitarians cannot derive much support from SCOTT's authority. After what he says against the buildings in the New Town we need not wonder when we read that at the close of his life, when he was in Rome, he preferred to visit an old Mediæval castle at Bracciano, and to examine every part with the greatest attention, and to make pilgrimages to Frascoli, where Cardinal YORK, the last representative of the STUARTS, lived, rather than to look at the works of MICHEL ANGELO and RAPHAEL at the Vatican. For the castle and the village bore some relation to Mediæval Scotland, to rank and birth, while the painters' works would recall the drawings or the prints on the walls of the detestable and dangerous if comfortable houses which, like an exhalation, were constantly arising outside the old city, which was more than ever in his thoughts.

### THE TRANSMISSION OF POWER IN FACTORIES BY ELECTRICITY.

BY F. J. WARDEN-STEVENS, A.M.I.E.E.

A PAPER dealing with the above subject was read by Mr. S. V. CLIREHUGH, before the Northern Society of Electrical Engineers, on Monday, May 17.

The paper referred more particularly to the textile trades, but the results are applicable in a great measure to timber and other mills, and for wood-working factories, and are therefore of interest to those connected with the building trades.

Mr. CLIREHUGH commenced by stating that he wished it to be distinctly understood that he did not think that electricity would in any great measure supersede mechanical transmission of power in factories used for textile work, as some people had supposed. Cotton mills, in particular, had such a good and steady load that only about 20 per cent. of the brake horse-power is wasted in transmission, and the coal bill is only 2 lbs. per horse-power hour. Even if the loss is 50 per cent., when such economical engines are used the saving is hardly sufficient to make it worth while to adopt electricity.

There are, however, other trades in which this is not the case, where the margin of loss in the distribution of power is so enormous as to effect a large saving even if the loss is only reduced by 20 per cent. The dyeing, bleaching and printing trades, in the author's opinion, use more coal per brake horse-power than any other trades in the world. The machines used for these purposes are driven by isolated engines of small size. The reason for this is that the speeds required are so varied that no reasonable form of speed gearing is known which would accomplish this variation of speed required. He also says it is necessary for the attendant to have the apparatus under his immediate control.

The losses in these small engines are so great that no more inefficient arrangement can be devised, and the adoption of electricity *must* save something.

We entirely agree with Mr. CLIREHUGH when he says that the unwisdom of the British manufacturer is in saying that he cannot afford to carry out improvements because

"trade is bad and profits low," while in Germany it is just at that time that improvements are introduced, and the trade improved and profits increased owing to the lower possible price of production. He also speaks of the suspiciousness of the British manufacturers, and says it is probably due to the great number of times they have been deceived by the travellers in oil, patent firebars, &c., which will, it is claimed, save half their coal bill.

Mr. CLIREHUGH then goes on to give his ideas on the particular form of plant suitable. He declares for direct coupled plant, medium speed, the dynamo being, in the larger sizes, multipolar. He also recommends shaft governors and ejector condensers. The engine should be of the inverted vertical enclosed type, with piston valve for high-pressure cylinder and a balanced slide valve for low pressure, and the lubrication should be under pressure. The dynamo recommended for 200 brake horse-power should be of the six-pole type with a slot-wound armature. We think it a rather extraordinary proceeding to lay down hard-and-fast lines in this manner, and one which is obviously unwise. For instance, the type of engine chosen is not the only one which would give very good results, as there are many other types which would give as good or better for this class of work. We think that due consideration should be given to the special circumstances and conditions of the case.

With his remarks insisting on the importance of sparkless collection of current from the dynamo, and with the result he expects, viz. 30 lbs. of steam per kilowatt, or  $2\frac{1}{2}$  lbs. of coal per indicated horse-power hour, we agree. He also insists upon the need of generating plant which will run continuously without heating or breaking down.

The important part of the paper now follows, and this refers to the size of a motor for any particular machine.

He speaks of the difficulty of obtaining information from the machine makers; they do not know, but have an idea that an engine of a certain size works with the machine. He points out that the indicator diagram is of no use, owing to the leaky glands, and the fact that the engines usually run with the drain cocks open because of wet steam. The diagrams show no signs of cut-off or expansion. The maximum normal power is a very difficult thing to arrive at, and is the most important point. The increased power required at starting, or exceptionally for a few seconds, is not of much importance. A motor will give almost unlimited power for a few moments, but the power over, say, five minutes is of great importance. The heating effect then rapidly comes into play and limits the power safely obtainable. He says that the best way is to measure the power taken by a motor driving the machine temporarily for a considerable time, several hours at least; the longer the time and the more nearly the work approaches to the usual the better. He further goes on to recommend the Royce time-fuse, and says that it will protect any motor which is at all suitable for hard work. It may be adjusted so that the motor can exert, say, 50 per cent. more than its normal load for any time up to three or five minutes without the fuse blowing, and this is the condition met with in practice. These time-fuses enable a check to be kept on the condition of the machine and the way it is used, and any great increase in the power required, due to the machine being dirty or improperly used.

Mr. CLIREHUGH also expresses the opinion that much power might be saved if machines were designed for running with electric motors, as wasteful gearing could be dispensed with.

The part of the paper which relates to gearing of motors to machines is of great interest. Three methods are mentioned as available when a motor running at 1,000 revolutions per minute has to be connected to a machine running at 50 revolutions per minute:—(1) Worm-gearing; (2) double reduction-spur; (3) single reduction-spur and belt. "It is undeniable that each of these methods may be satisfactory under certain conditions, but as it is always desirable to keep the speed of the motor up to that mentioned, it will be found that the peripheral speed of spur-gearing is too great." He mentions that the highest peripheral speed at which the best cut spur-wheels will run silently without wear is about 1,800 feet per minute. Belts are objected to owing to damp and space occupied, and he states that the worm-gearing is the most satisfactory, when made in the

best manner, for such a large reduction in speed. The results of a test are given, which show that the worm-gearing is practically as efficient as a belt drive. We think this result cannot be accepted entirely, as there are several points of difference in the conditions, but it shows at least that the worm-gearing is fairly good and that, taking into consideration the small space occupied, it is very suitable where large reductions in speed are required.

The use of enclosed motors is recommended in most works, and in some of the wet positions the motors should be water-tight as well.

Carbon brushes are condemned with low voltage motors, but a wholesale condemnation such as this we cannot agree with. If a motor is exceptionally well designed and expensive, there is no doubt that they are unnecessary, but it is a fact proved by theory and experience that carbon brushes will make it possible to run cheap motors without attention, which could not otherwise be used at all. Referring to the means of varying the speed of the motors within wide limits, the use of water resistances to reduce the speed for any time is condemned, owing to the trouble caused by evolution of gas, &c.

Again, in connection with the wiring of buildings, one system is broadly recommended, viz. that of fixing insulated wire on insulators. These broad statements are useless, as the kind of system must depend upon local conditions.

Referring to the cost per motor installed, the power of the motors varying from three to twenty, he finds that for enclosed motors it works out to be about 235%, and for open motors 217%. He then goes carefully into the losses and gains with electric transmission when compared with the use of small engines. A few of the statements may be of interest.

The capital cost of an electrical transmission is about double that of small steam-engines. From Mr. BRYAN DONKIN's tests small steam-engines use about 150 lbs. steam per horse-power hour. The engine to be used for electric transmission uses 20 lbs. of steam per brake horse-power hour. The losses from engine-shaft to motor—dynamo 5 per cent., transmission (cables) 2 per cent., motor losses 5 per cent., gearing losses 8 per cent.; total, 20 per cent. We think these losses rather too low, especially as the engine and motor will seldom run at their full load. He states further that if you use half the coal you only require half the stokers and half the boilers. The maintenance costs with electricity have been certified by several owners on the north-east coast to be only 20 per cent. of that with steam.

In conclusion, although the figures given and some of the arbitrary recommendations are not wholly acceptable, the paper is a valuable contribution to this subject, and is well worth reading by those interested in the reduction of the cost of power in workshops and factories.

## THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Architectural Association was held on Friday evening last, Mr. Beresford Pite, president, in the chair.

The following officers were elected for the ensuing year:—President, Hampden W. Pratt; vice-presidents, Banister F. Fletcher and A. H. Hart; committee, A. Beresford Pite, G. H. F. Prynne, R. S. Balfour, F. G. F. Hooper, F. T. W. Goldsmith, W. H. Seth-Smith, H. B. Cresswell, C. De Gruchy, T. W. Aldwinckle and W. D. Caröe; hon. treasurer, H. W. Pratt; hon. librarian, C. H. Freeman; hon. secretaries, E. Howley Sim and G. B. Carvill.

The Architectural Association Travelling Studentship, 1897, was awarded to Mr. E. H. Evans by the unanimous vote of the prizes sub-committee. Mr. H. F. Waring's drawings were considered next in merit.

An exhaustive paper on "Plumbing and Sanitary Work" was read by Mr. S. S. Hellyer, a part of which will be found in the present number.

A vote of thanks was proposed to Mr. Hellyer by Mr. F. G. F. Hooper, who spoke upon the necessity of a more careful attention to sanitary arrangements in all houses.

Mr. G. H. Fellowes Prynne, in seconding the vote of thanks, spoke of the shortcomings of the present system of sanitary administration, and especially in the case of suburban villas.

Mr. W. E. Bland said that Mr. Hellyer was one of the pioneers of sanitation. Although he had long taken an interest in the subject, some points had never appeared to him in their true light until he heard the lecture just delivered.

The Chairman said genius had been defined as an infinite capacity for taking trouble. Lectures like Mr. Hellyer's were far more important than the ordinary lecture, and sanitation was made to appear more simple in its principles than they had imagined.

The vote of thanks was carried by acclamation.

Mr. Hellyer expressed his gratification at the attention given to him. He believed it to be the duty of the architect to make the house healthy, and it was not properly finished unless in that condition.

### CONFERENCE OF CIVIL ENGINEERS.

THE conference of the members of the Institution of Civil Engineers was opened on Tuesday morning at the Westminster Town Hall. Mr. J. Wolfe Barry, C.B., F.R.S., president, in a brief opening address congratulated the members who had taken part in the designing and construction of the Blackwall Tunnel upon the successful completion of that work. He then gave an outline of the career of the Institution, which dates from 1818. From the small beginning of 1818—which had not attained to a growth of 200 members of all classes in 1828, who, from difficulties of intercommunication between different parts of these islands, must have been mainly, if not exclusively, Londoners—there now number 6,200 members, associate members and associates, and 900 students, making a total roll of 7,100. It is not too much to say that in this past sixty years a new and most important profession has arisen, second to none in its responsibilities and in its value to humanity at large. A little more than 5,000 members are in the United Kingdom and 2,000 are abroad; and as almost all the students and most of the associates are to be found at home, therefore of the corporate members from one-half to one-third are in the colonies or dependencies or in foreign countries. Of the 5,000 members, associate members, associates and students in the United Kingdom, 1,950 of all classes are living or practising in the Metropolis. Though largely cosmopolitan as a society, the great value of the metropolitan headquarters or central home of the whole body was admitted. Experience amply proved how often absent brethren turned to it for advice, for reference, or for the support of their views and interests. Without this mutual interdependence the Institution would be but a poor representative of the profession. It was with the view of further strengthening the bonds of union that the Congress of this year had been instituted. It was a new departure, and much was to be learned with regard to conducting it to the best advantage, both for the important objects in view and for the convenience of the members who attend it. About 800 members expressed a wish to be present at the meetings, and of these a very large part are country members. The idea which we have had in view, said the President, is to encourage by all means the conversational interchange of ideas and knowledge rather than any set debates. I think that we engineers as a body are always ready to give our brethren the benefit of any experience or knowledge which we may have happened to gain. I do not think that ours is an acrimonious profession; we may have our contests before tribunals of various kinds, but I think we are free of mean jealousies and of what I may almost call the crime of importing personal animosities into our professional struggles. Dr. Johnson says, "Knowledge is of two kinds; we know a subject ourselves or we know where we can find information upon it." I think this Congress will be useful in the direction of both these descriptions of knowledge, and that nothing can be better for those who are facing new problems than being able to meet and discuss their progress or their difficulties. Again, we have thought that a Congress would be very beneficial as bringing about an acquaintance with the personality, as well as with the work, of so many who up to now have not had the advantage of meeting each other. I should like it to be distinctly understood that any repetitions of this Congress, so far as my views and the views of the present Council are concerned, will be like this, namely, a metropolitan Congress. It is not intended to be a peripatetic Congress, meeting this year in London and another year elsewhere. The object which we have had before us is to bring those who live out of London into London, not to take Londoners and others elsewhere. I think any other object would be undesirable. London is so large that it is naturally the centre to which all local associations can occasionally turn with advantage to themselves and with manifest benefit to Londoners. Further, it contains what I have justly termed the home of the Institution, associated not only with so much of present interest, but still more with the important memories of the past—with Telford, Walker, Rennie, the two Stephensons, Brunel, Locke, Vignoles and others who have gone before us, and with so many of the fathers of the profession who, happily, still adorn our Society. The home, further, contains our unrivalled library and a fund of engineering information. Lastly, by arranging the Congress

at the usual time for our annual conversazione, we are able to meet socially and to show some hospitality to our brethren. All these considerations point, in my opinion, unmistakably to London as our rallying-point, and I see no reason for any other arrangement.

In section I., railways, Sir Benjamin Baker took the chair, and the subject of rails and permanent way was introduced by Mr. H. Copperthwaite, who restricted himself to the proper material for sleepers and the weight of steel rails. Timber creosoted sleepers, in his experience, are the best. Steel and iron sleepers have been tried, but the results generally have been disappointing. Jarrah and Kauri, two hard Australian woods, are about to be tried, and it is anticipated that they will prove a success. The weight of rail is a difficult point to settle, but a steel rail of about 80 lbs. per yard appears to be about what is now wanted. The subject of permanent way was introduced by Mr. F. W. Webb, of the London and North-Western Railway, who, in improving the permanent way on a portion of that system some years since, introduced a bull-head section of rail in place of the double-head section, and a deep fish-plate for the joints. Other details were also improved, and the system had worked satisfactorily down to the present time.

Section II. dealt with harbours, docks and canals. Mr. Harrison Haytor took the chair, and Mr. John Kyle introduced the subject of concrete in relation to marine work. He treated the subject under three heads, namely, the treatment of concrete in the yard; the treatment of mass-work under water, and the treatment of block-work under water. Having had over forty years of practice, during which time he had handled over 1½ million cubic yards of concrete at home and abroad, Mr. Kyle was enabled to bring a number of interesting and useful facts before the section. Mr. A. E. Carey was equally interesting in his communication on the same subject, treated from the standpoint of his experience. Mr. H. F. Donaldson covered a wide field in his communication treating of the arrangement of docks, with special reference to the formation and maintenance of their approaches.

In sections III. and VII. Mr. W. H. Preece spoke on the transmission of power by electricity. In this communication he broadly discussed the relative efficiency of three effective modes of transmitting power, namely, electricity, water and air. Naturally Mr. Preece has a predilection for electricity, and he gave some satisfactory examples of its application, showing its many and marked advantages. He instanced some cases in which it would have been impossible to transmit power otherwise than by electricity, which power for long distances carries off the palm. Mr. E. B. Ellington followed with a communication on the transmission of power by water, in which all the advantages of that method were pointed out and its special applications described. For intermittent work it was shown to be well suited, but its cost is altogether too high to displace private steam plants, except in special cases. Dr. John Hopkinson then introduced the general subject of the transmission of power by ordinary gearing and shafting, by ropes, by compressed air and by steam, comparing them with electricity and water and pointing out that each had its own field. This in fact was the conclusion deducible from the long and animated discussion upon the three communications. There was a general admission that every system had its own merits, but that for long distances electricity was the best.

Mining and metallurgy were discussed in section IV., with Mr. T. Forster Brown as chairman. Mr. J. B. Simpson greatly interested the meeting in the information he imparted in the matter of dealing with water in pits during sinking and in permanent work, giving some useful examples of his practice in these respects. Mr. Henry Davy dealt with the cognate question of water in deep shafts, explaining the oldest method of dealing with the matter, which is the Cornish, and proceeded to describe the more modern systems in general use. Mr. Bennett H. Brough introduced the subject of deep levels in mining practice in the United Kingdom. In Great Britain the deepest colliery is at Pendleton, near Manchester, the deepest workings being 3,474 feet below the surface. The deepest metal mine is Dolcoath, Cornwall, which has reached 2,582 feet. These enormous depths have, however, been largely exceeded in other countries, notably in the Lake Superior copper region, where the Red Jacket Shaft of the Calumet and Hecla Mine has now attained the record depth of 4,900 feet. The prospects of deep mining in Cornwall were considered by Mr. William Thomas. Comprehensive schemes for placing the equipment of the leading Cornish mines on a more satisfactory footing are being carried out, and the prospects of deep mining are proportionately improving.

Section V. (shipbuilding) was presided over by Sir William White, and Mr. Archibald Denny introduced to notice the practical application of model experiments to merchant-ship design. He described the Leven Shipyard experimental tank and apparatus and the manner in which the experiments were practically applied in ship-designing.

In Section VI. questions relating to waterworks, sewerage

and gasworks were dealt with. The chair was occupied by Mr. James Mansergh, who introduced the subject of the law and allocation of underground water. The subject proved of great interest to waterworks engineers, as the principle involved has been a matter of discussion before a Commons committee within the last few weeks. He showed that the law relating to underground water was confessedly so difficult to interpret and so likely to operate unjustly that it required some amendment.

The afternoon was devoted to visits to electric-lighting stations, gasworks, waterworks and hydraulic-power works in and around the Metropolis.

### PREHISTORIC MAN IN ENGLAND.

IN his last report on the Geological Survey of the United Kingdom, Sir Archibald Geikie, the director-general, writes:—

Excavations and borings undertaken last year by Mr. Reid at Hoxne, with the aid of the British Association and the Royal Society, have thrown a good deal of light on the question of the relation of man to the Glacial epoch. He has now proved that the Palæolithic period is certainly newer than the period of intense glaciation represented by the chalky boulder-clay. He has also found that between the two came a mild epoch, when a temperate flora flourished in Suffolk, followed by a cold epoch, when only dwarf Arctic plants could endure. The evidence agrees closely with that obtained during the geological survey in Sussex and Hampshire, where also Palæolithic gravels are separated from the period of maximum glaciation, represented by the "Selsey erratics," by fluviatile deposits containing remains of animals and plants indicative of temperate climate. The whole of these recent researches tend to show that the earliest satisfactory evidence of man's appearance in this country indicates a date considerably later than has often been supposed.

At the close of the season Mr. Reid paid a brief visit with Mr. B. Harrison to the part of the North Downs where that gentleman had obtained the extremely rude and doubtful "implements" about which a good deal has lately been written. The pits that had been opened were, unfortunately, too much obscured by the falling-in of the sides to allow of proper examination; but the evidence for the supposed extreme antiquity of the deposit seemed to rest more on the geology of the surrounding area than on the character of the sections.

An examination of the plateau shows that the dip-slope which extends from the chalk escarpment to the Thames has been greatly modified by the excavation of numerous "coombes," which fall towards the north. As these coombes, like those of the South Downs, nearly all commence close to the continuous ridge of the escarpment, without cutting through it, they appear, like those of Sussex formerly described by Mr. Reid, to have originated since the escarpment was in its present position. It is clear, also, that if the dry chalk-valleys of the South Downs were excavated by floods caused by the impervious nature of the frozen soil at a period when the climate was colder, the same reasoning must apply to the North Downs. The gently-sloping plain and slight hollow near Parsonage Farm is, in Mr. Reid's view, exactly one of those places where gravel formed from the reconstruction of the clay with flints, Eocene and Pliocene strata, might be expected to have been deposited in late Pleistocene times. Elevation above the sea-level, or above adjoining valleys, under such Arctic conditions, would be no test of the antiquity of the gravels. These might obviously have been deposited at any level and over rocks that are now pervious and no longer liable to floods if the winter climate were severe, the slope gentle and the area dominated by land somewhat higher.

Mr. Reid would therefore correlate these plateau-gravels of the North Downs with the implement-bearing gravels of Sussex and the Thames Valley, and would suggest that the rude character of most of the implements—if implements they be—may be due to the weathered surface, the flints from which they were made having been toughened by weathering, so that they could only be battered, not flaked. It is well known to every road-surveyor that flints picked off a field are much tougher than those dug directly out of the chalk, for not only have they gone through an annealing process, but they are survivors after the weather has destroyed those that contain flaws. The surprising point is not that implements should occur in these gravels, but that good implements should be so extremely rare.

The occurrence in the plateau-gravels of fragments of Ightham stone points to their transportation across the area now occupied by a deep east and west valley. The date of that transportation is not yet known; but the discovery of much Greensand and Purbeck chert in the Bagshot sands of the Hampshire Basin suggests that in the North Downs also it may date back to Eocene times. In the older Pliocene period, also, a plane of marine denudation seems to have connected the

Greensand and chalk areas. Thus during two periods at least Greensand chert may have been transported to the North Downs. Its final deposition in the gravels near Parsonage Farm is probably only the last of many removals to which the fragments have been subjected.

Whether any part of the existing sheet of clay with flints remained undisturbed in the Glacial period is very doubtful, and this deposit certainly overlaps and contains material from both Eocene and Pliocene strata. The discovery even of undoubted Palæolithic implements at a considerable depth in clay with flints would be insufficient to carry back the antiquity of man beyond the last period when the soil was frozen and the higher downs were subject to torrential action.

### THE SILCHESTER EXCAVATIONS.

IN 1890 the excavations on the site of the Romano-British Calleva Atrebatum of the Antonine Itineraries were commenced, and the results are regularly shown at the rooms of the Society of Antiquaries. The site has been divided into squares, and Numbers XV. and XVI. were the fields of the operations for last year's work. Number XV. appears, like several of the others, to have been given up to the dyeing industry, of which traces were found in 1894 and 1895. It contained two houses, one of large size, and four other blocks of buildings, as well as the remains of several hearths and furnaces, and it is conjectured that a large area towards the north was used as a bleaching-ground. One valuable discovery was that of two wells, one with a wooden framing at the bottom, and the other with a large wooden tub. The latter is in very tolerable condition, and will be added to the Silchester Loan Collection in the Reading Museum. The well was sunk in the native soil to the depth required to reach the water supply. A square curb, formed of 6-inch square oak baulks about 4 feet long, dovetailed together, was laid on the bottom. Upon it rested a round tub or barrel 3 feet in diameter, made of fir staves 3 feet 9 inches long by 5 inches wide, the whole hooped with birch hoops. A second tub was stood on the top of the first, and the interspace between the tubs and the sides of the well was filled by pugged clay well rammed in. Above this the well was steened with flints.

Although the past year's work has not exhumed any such extraordinarily magnificent edifices as those found previously in Insula XIV., the examination of Insula XVI. has produced a large and important house of the courtyard type and two other houses of the corridor type, as well as an isolated square building, and traces were found of what were probably structures of wood. The collections of glass, pottery, bone and metal articles, coins, &c., are not less numerous and interesting than usual. Roman wood relics are always rare by reason of the perishable nature of that material, and therefore the leg of a domestic stool in turned hardwood, although broken, is a cherished rarity. Many slabs and smaller portions of Purbeck marble, and of a purple, green and white Pyrenean marble used in architectural constructions, have been obtained. Some of the former are from the tribunes of the basilica or law courts. A small fragment of Egyptian porphyry, probably from a broken vase or other ornament in one of the temples, was found near the east gate. One fragment of glass with green and yellow eye-spots in a deep brown ground is particularly beautiful, and a perfect white-ware bottle-necked vase is of very elegant shape. In one pit were found a large number of sheep's bladebones, the perforations in which showed that they had been used for rings and counters; and among the minor objects were a small Doric capital, a handle of a bowl of millefiore glass, two bronze bells, the bronze covering of a casket and four gilt brooches.

The most striking discovery, however, was of a cutting about 6½ feet deep, outside the city and leading to the wall. Towards the east end were found remains of iron collars, at regular intervals, which showed that a wooden pipe had been laid in the cutting. These collars were used to join the several parts of the piping together, and the joint was probably made watertight by some kind of cement. Nothing of the kind has been found elsewhere in this country, but a precisely similar discovery was made in France in 1872 on the site of a Roman town at Chatelet, between St. Dizier and Joinville, in Champagne, of which an account was given by M. Grignon, who carried out extensive excavations there by order of the king. The tracing of the pipe led to the discovery of a hitherto unknown gate in the city wall, which bears a striking resemblance to one discovered near Aldersgate Street when the new Post Office buildings were erected. The gate had a single opening 12 feet wide, which had been reduced to 7 feet by blocking it with masonry. There was a ditch outside, traversed by a wooden bridge, supported midway on wooden pillars resting on a gravel bank. The part of the bridge adjacent to the gate was probably either a drawbridge or one which could easily be destroyed, so as to render an attack impossible. The piping below led to Insula III., where there is an unexplored building which will be examined next season, and where it is conjectured

that the principal or most used baths of the city were situated. The gateway is a very durable structure of rubble and large flat stones.

The explorations to be next taken in hand are those of the Insulae XVI. and XVII., and the site of the buried building in Insula III., into which the water conduit from the postern ditch was carried. The executive committee of the Silchester Excavation Fund, therefore, have a more than usually expensive task before them by reason of the greater depths to which the excavations will extend.

The balance-sheet shows an expenditure of about 500*l.*, of which 333*l.* went for wages and 61*l.* for carpenters, &c., and a balance in hand of 13*l.* 15*s.* 8*d.* Subscriptions are invited, which may be paid either to the hon. treasurer, Mr. F. G. Hilton Price, 17 Collingham Gardens, or to Mr. W. H. St. John Hope, the hon. secretary, at Burlington House.

### SOUTH KENSINGTON MUSEUM.

THE select committee appointed to inquire into and report upon the administration and cost of the museums of the Science and Art Department have presented the following first report on the protection of the South Kensington Museum from fire:—

1. Your committee are making progress in the inquiry entrusted to them. But they consider it to be their duty to make an immediate report to the House of Commons on the peril of destruction by fire to which the priceless collections at South Kensington Museum are exposed.

2. There are a number of old buildings, built of wood and lath-and-plaster, and in some instances covered with tarred felt, in close proximity to the modern permanent buildings which contain the bulk of these collections; and the danger has been aggravated by the erection of large temporary buildings constructed of fir framing, covered, it is true, on the outside with iron, but lined internally with varnished match-boarding.

3. Attention has repeatedly been called both in and out of Parliament to the risk to which these collections are thus exposed, but the state of things above described goes on from year to year.

4. The roofs of the galleries in which the Sheepshanks and Jones collections, the Chantrey bequest, the Water-Colour Gallery and the Dyce and Forster collections are housed are constructed mainly of unsuitable timber, and are especially open to fire damage, from the fact of having wood-lanterns, skylights and open sidelights. The walls are boarded and canvased, with a space behind. The sparks from a conflagration of the old or from the temporary buildings might occasion irreparable damage to these collections from fire or water used to extinguish it.

5. Opposite the Raphael Cartoon Gallery there is a staircase with a wooden roof and wooden stairs and partitions. In one of the eastern picture galleries there is a door which opens into a wooden staircase leading to the roof, with a large amount of wood partitioning. These would, in the event of fire in other parts of the premises, be sources of imminent danger to the collections.

6. The Art Schools, which adjoin these galleries, are from their construction and from their necessary use specially liable to the risk of fire.

7. The private residences of the officers of the Department in the immediate vicinity of the galleries are a further source of danger. The whole of the floors are of wood; the partitions running up and dividing the upper storeys are of wood, the staircases are of wood, and the roofs are also of wood. The party walls dividing the residences have not been carried through the roof. There are eighty-one open fireplaces. These premises cannot be watched day and night by the police and attendants, as the other buildings are, and a domestic accident, such as might happen in any London house, might at any moment be the beginning of a conflagration.

8. The entrance to the southern galleries on the west side of the Exhibition Road is a highly dangerous structure. It is timber-framed and weather-boarded and covered with tarred felt.

9. The southern galleries themselves would fall an easy prey to fire. They are of slight construction, are open from end to end, one side is almost entirely window openings, and wood is entirely used in the fabric for floors, roofs, divisions and staircases. Should fire seize a portion, the great probability is that the whole would become a heap of ruins in a very short space of time.

10. Dangerous as these galleries are in themselves, they are exposed to still greater risk from the flimsy temporary buildings which adjoin them.

11. That the buildings in which the collections at South Kensington are placed have enjoyed so long a comparative immunity from fire is due to the care and vigilance of the police, the skill and care of the various attendants and mechanics employed about the premises, and the unremitting

watchfulness of the officials. The erection and continuance of such buildings as are about the site have almost courted disaster.

12. That the principal structural alterations necessary for the protection of the collections from fire have not been made appears to be due to the fact that the completion of the permanent buildings of the South Kensington Museum has always been in the contemplation of successive Governments, as the true remedy for the danger of destruction from fire which hangs over the collections so long as they have to be partly housed in the present temporary structures.

13. This necessity of providing buildings suitable for the exhibition of the objects of art and science collected at South Kensington has been long under the consideration of successive Governments. Your committee regard it as their immediate duty to lay before the House of Commons by means of an interim report their very strong opinion that permanent buildings for the adequate accommodation of the collections at the South Kensington Museum should be proceeded with without delay. They are of opinion that it will be a source of grave discredit to the country if the settlement of this matter, which has been the subject of consideration by Government for many years, and of endless correspondence between the departments concerned, is any longer delayed.

### EDINBURGH ARCHITECTURAL ASSOCIATION:

THE Edinburgh Architectural Association visited on Saturday last The Binns and Midhope, Linlithgowshire, by permission of Mr. J. Cornwall Dalryell and the Earl of Hopetoun. Mr. Thomas Ross, F.S.A.Scot., in describing The Binns, said that it occupied a charming situation on the summit of a low ridge of hills to the south of Blackness Castle. On plan it formed three sides of a square, the east wing being the oldest part, and probably dating from the sixteenth century, and the north and west wings from the seventeenth century. One, at any rate, of the fine plaster ceilings seemed to be by the same hand that executed those at Moray House, Edinburgh. The Dalryells of The Binns were descended from the Dalryells of Dalryell, and they acquired The Binns towards the end of the sixteenth century. General Dalryell took a most prominent part in the events of the seventeenth century, dying a very old man in 1685 in spite of a large reward being offered for him, dead or alive. Mr. Ross, in his description of Midhope, said it was a lofty mansion-house situated in a picturesque dell, and quite hidden from view till one was almost within call of it. Oblong on plan, it was erected at three distinct periods. The whole basement was vaulted, and a small newel stair in the older part and a fine oak stair in the latter gave access to the upper floors. Alexander Drummond, second son of Alexander Drummond of Earnock, was the first laird of Midhope, and in the beginning of the seventeenth century the property passed into the hands of the Livingstone family, who probably built the eastern parts.

On the motion of Dr. Rowand Anderson, a vote of thanks was passed to Mr. Dalryell, the Earl of Hopetoun and the leader of the visits, Mr. Thomas Ross.

### THE SHEFFIELD TOWN HALL.

THE Sheffield Town Hall was on Friday last formally opened by the Queen. On Her Majesty's arrival an address was presented in which the Corporation expressed their grateful rejoicing that the dedication of the home of the municipal government in the city would for ever link Her Majesty's name with the history of Sheffield, and through far-off years would strengthen the bonds with which a grateful and ever-growing loyalty shall bind the subjects to the throne. The address was presented in a gold casket by the Duke of Norfolk, the mayor.

Her Majesty gave the following written reply to his Grace:— I have great pleasure in receiving your loyal and dutiful address, and in being able to be here to open this spacious and beautiful Town Hall, which is a worthy monument of the vast growth and importance of your city. I am glad to associate myself with an event of such moment to Sheffield as the dedication of this fine building to municipal uses; and I trust that the progress and the prosperity of the city and the welfare of its inhabitants may be great and uninterrupted. I fully share in your appreciation of the manifold blessings of peace and prosperity which have during the last sixty years been vouchsafed to my Throne and Family and to all classes of my subjects, and I am deeply touched by the numerous manifestations which reach me of the wish to associate these blessings with my reign. With profound reverence and thankfulness, I join in your praise and gratitude to the Almighty, who has sustained and blessed this kingdom and Empire during the long period for which the responsibilities of the sovereignty have lain upon me.

The architect was presented to the Queen. The ceremony lasted twenty minutes.

## NOTES AND COMMENTS.

THE name of ROBERT THOROTON, M.D.; of Car Colston, who died in 1678, is associated with the history of Nottinghamshire. When it was decided to found a society for the study of the history and antiquities of the county of Nottingham a more appropriate name could hardly be found than "The Thoroton Society." The first meeting is to be held in the Shire Hall, Nottingham, on June 1, with the Duke of ST. ALBANS, Lord Lieutenant, as chairman and first president. The funds obtained by the subscriptions of members (10s. 6d. annually) are to be devoted to promoting the objects of the Society and printing historical matter. The vice-presidents nominated are the Duke of PORTLAND, the Duke of NEWCASTLE, the Earl MANVERS, the Bishop of SOUTHWELL, Lord BELPER, the Mayor of NOTTINGHAM, the Dean of ST. PAUL'S, Mr. J. E. ELLIS, M.P., Mr. JOHN G. B. THOROTON-HILDYARD. The honorary secretaries are the Rev. JOHN STANDISH and Mr. W. P. W. PHILLIMORE, and Lord HAWKESBURY will be Chairman of Council. The new Society is deserving of support, and is likely to render yeoman's service to local archæology.

ALTHOUGH railways have been in use in this country for three-quarters of a century, it is still uncertain what kind of timber should be specified for sleepers. Fir is almost universally employed, and generally creosoted. When creosoted sleepers last from twelve to fifteen years, and so long as rails only last about the same time there is no need for better material; but, with the adoption of steel rails, there is need of sleepers of greater endurance, and cast-iron, wrought-iron and steel have all been tried. But they have caused disappointment, the greater first cost not producing any proportionate added life. The Australian woods, Jarrah and Kauri, have been suggested, and a trial is to be made of them. The remarkable endurance shown by these woods when employed for street paving encourages the hope that they will be equally efficient in railways. A great many sections of rails have been rolled, but only two, the vignoies, or flat-footed, and the bullheaded, are in use, and the vignoies section is rarely seen in this country. Mr. COPPERTHWAIT, of the North-Eastern Railway, is of opinion that if a life of about twenty years were adopted for steel rails on ordinary railways, it would be a waste of material to use a section weighing more than 80 lbs. per yard lineal. Mr. F. W. WEBB, of the London and North-Western Railway, introduced on that system the bullhead section of rail, a deep fish-plate, and screened the ballast so as to keep the road-bed as dry as possible. As a heavier rail is about to be introduced, he has suggested a joint in which the defects of the ordinary fish-plate joint seem to have been overcome, and the usual fish-plate holes through the rails are rendered unnecessary.

At the last meeting of the Wandsworth Board of Guardians the special committee on the Nurses' Home reported that they had requested Mr. ALDWINCKLE to give his aid in the selection of the sixteen designs submitted in competition, his fee being twenty guineas. It was decided that the design marked "Nightingale," by Messrs. LONSDALE & HARRISON, was entitled to the first premium of fifty guineas; that the design marked "Florence Nightingale," by Mr. F. J. W. GOLDSMITH, was entitled to the second premium of twenty guineas, and the design marked "Victoria," by Messrs. GOLDWILLS & BULMAN, to the third premium of ten guineas. It was further recommended that Messrs. LONSDALE & HARRISON'S design should be carried out, subject to such alterations as Mr. ALDWINCKLE had suggested. The Board of Guardians adopted the recommendations of the committee.

THE object of the Conference of the Institution of Civil Engineers is to make members more or less acquainted with the latest development of practical science. The paper which was read by Mr. ROGERS FIELD on "House Sanitation" at the meeting on Wednesday suggests that civil engineers are as yet in the elementary stage; and it

will be long before they are competent to undertake the charge of domestic sanitation. The author said the subject was well worth attention. There should be an ample supply of pure water to the house, and appliances for distribution should be so arranged that it could not be contaminated before it was used. In drainage the two chief guiding principles were:—(1) That all foul matter directly it was produced must be rapidly and completely removed from the house; and (2) that there must never be any passage of air from the drains or waste pipe into the house. The drainage must be self-cleansing and readily accessible. He found it advantageous to use heavy cast-iron pipes instead of stone-ware pipes. Gas pipes and fittings were as a rule leaky, and allowed a constant escape in the house, which might cause serious outbreaks of sore throats. The pipes and fittings should always be tested by pumping air into them and watching the result on the pressure gauge. Who would have expected that it was necessary to explain to the foremost body of engineers in Europe a few facts with which it was supposed every child in a Board school was acquainted? Mr. ROGERS FIELD'S experience would have enabled him to say much more about sanitation, and that he started at so low a level does not say much for his estimate of the knowledge of his fellow-members.

WHEN MOORE, the poet, said that two thousand years had passed without any improvement in the cabins of the Irish he was not exaggerating. Unfortunately the dwellings of the agricultural labourers in many parts of England appear to be no less unfitted to shelter human beings. According to what was stated at a conference of the Land Law Reform Association on Tuesday, an inquiry into the condition of sixty-seven villages had demonstrated that among 270 cottages one-fifth were bad or extremely bad; 61 per cent. of the bedrooms had no fireplaces, consequently no proper ventilation; one-sixth of the cottages had bad and dangerous water-supply, and in some cases were without any supply. In another direction 247 villages were examined. In one-half of these villages were bad cottages, one-fifth had insufficient cottage accommodation, in many there was gross overcrowding, and in one-sixth there was totally inadequate or dangerous water-supply. With so many impressive facts before them, the Conference could hardly decline agreement with the following resolution:—"That this Conference is of opinion that the condition of the housing of the working-class population in a large proportion of the villages of England and Wales constitutes an evil of serious public importance. It considers that measures are needed which shall provide effective remedies for the unsatisfactory sanitary state, the bad repair and the insufficient accommodation of many of the existing cottages; which shall make it possible to replace the dilapidated buildings that are still inhabited by new and convenient houses; and which shall assure to the labourer some degree of security in the tenure of his home." The remedies are costly, and the difficulty is to discover where the money is to be found. Land is not everywhere profitable, and the additional taxes imposed by county and parish councils do not diminish the burthens on it. All the Conference could devise was to recommend that authority should be given to those councils to raise loans for acquiring land on long lease on which to build cottages with gardens attached, and to delegate the management to the councils or to committees. That would signify that where landlords are indifferent other people would be mulcted to house the landlord's labourers. If cottages are provided at the public expense why not also add food and clothing?

## SIR A. W. FRANKS.

THE president of the Society of Antiquaries, Sir Augustus Wollaston Franks, K.C.B., died in London on Friday after some weeks' illness in his seventy-second year. According to the *Times*, he was the elder son of Captain Frederick Franks, R.N., and Frederica, daughter of Sir John Sebright. He was born in 1826 at Geneva, where, and at Rome, his parents lived during his boyhood, and was educated at Eton and at Trinity College, Cambridge. Even in his college days he developed the taste for Mediæval archæology upon which in later life he became the leading authority, and he published in 1849 a volume of "Ornamental Glazing Quarries," containing many drawings by his own hand. At the same time he began his extensive collection of rubbings of monumental brasses which was eventually presented to the Society of Antiquaries. He acted as secretary of the exhibition of Mediæval Art held at the Society of Arts in 1850, the first of many similar displays, and it was probably the knowledge of the subject he then showed that led Mr. Hawkins, the keeper of the Department of Antiquities at the British Museum, to propose that he should enter the Museum as an assistant, which he did in the year 1851. The department was then a mere collection of odds and ends; when Sir A. W. Franks retired it occupied more than one-half of the upper floor of the building. The post of principal librarian of the Museum was offered him, but he declined it, feeling that his proper vocation lay in his own department. He was a man capable of warm friendships, which was in itself a benefit to the Museum, and it may safely be said that it is to his friendship with Mr. Henry Christy, Mr. Felix Slade, Mr. John Henderson and Mr. William Burges, and to the advice and help that he gave them in forming their various collections, that the Museum owes their valuable bequests. To him was due the comparatively recent purchase of the Royal English gold cup; he actually bought it himself from Messrs. Wertheimer, and it was only the consideration that his purchasing powers would be curtailed for some time that decided him to appeal to others for help in keeping it for the nation. Other sections besides his own bear witness to his catholic taste and great liberality, and he was not infrequently requested by Government to give his judgment on proposed purchases. As soon as his retirement from the Museum became inevitable under the Order in Council he was placed on the standing committee, and took up to the time of his death an active part in the business of the Museum. He was for some time director of the Society of Antiquaries, a post involving the editorship of the Society's publications, and in 1891 he was nominated President for the usual period of seven years. The Society as well as the Museum was familiar with his liberality, and quite recently he presented to the Society some hundred volumes from his antiquarian library. Many struggling antiquaries and others can testify to his generosity, both with his varied knowledge and his purse.

His chief collections are of Chinese and Japanese porcelain and English pottery and porcelain (both presented to the British Museum); drinking vessels of all materials, and Japanese works of art (both on loan at the British Museum); continental porcelain (now exhibited at the Bethnal Green Museum); rings and gold ornaments—the rings forming undoubtedly the finest collection in existence; and bookplates. The latter collection was the amusement of his later years, and is due to his intimacy with the late Lord de Tabley, who was the first to take up the subject. It is probably the largest and best in England. At the Fountaine sale Sir A. W. Franks joined the syndicate of gentlemen who secured for the nation the objects now in the South Kensington and British Museum. In order to give the Trustees of the British Museum a lever to use with the Government he offered to give objects equivalent in value to the special grant asked for. The works of art he then presented were worth about 3,000*l*. His friendship with the late Lady Charlotte Schreiber led him to help her in her great work on "Playing Cards," and when Lady Charlotte's sight failed he undertook the completion of the book, the last volume of which appeared shortly after her death. His principal discovery in archæology was to separate the work of the age which produced what he called "Late Celtic" antiquities—perhaps the most artistic productions of any people who have inhabited this country—from that of the age which preceded and followed it. His persistency as a collector, moreover, managed to secure for the nation the best collection that exists of the remains of this period—a period which lies on the borderland between the prehistoric and historic periods in Britain, and about which antiquarian relics are our only means of knowledge. He had in hand at the time of his death a catalogue of the enamels in the British Museum—one of his favourite subjects. It is to be regretted that it was not finished, as a work on the subject is much wanted. Among his published archæological works may be mentioned the valuable catalogue called "Medallic Illustrations of British History," which he edited with Mr. Grueber in 1885, an edition made in conjunction with Dr. Latham of Mr.

J. M. Kemble's "*Horæ Ferales*," a volume which his additions converted into a standard archæological work, and a treatise on glass and enamel, which, though brief, is, with regard to the enamel, the most trustworthy treatise in English on the subject.

A HALF-CENTURY OF LINE ENGRAVING,  
1780-1830.\*

I WISH first to warn you that the breadth of the subject of my paper as indicated by its title will be found considerably narrowed in its delivery by reason of the limitation of time, and more so by the limitation which I have placed on myself, my object being briefly to call attention more particularly to one application of the art of engraving in England, which had its rise and decline within a period of half a century, a period, however, which produced in great quantity work which I believe to be worthy of careful study and of being carefully preserved.

Many of you probably are familiar, but I trust not with that familiarity which breeds contempt, with the little duodecimos, generally in shabby browns and often denuded of all the charm of gold-tooling and lettering, which once gave exterior beauty to the dainty little books, which enshrined the poets, essayists and novelists of the later years of the last century, and with the like-sized books in the brighter clothing of reds and greens and purples covering the collections of prose and poetry which, under the various names of *Bijou*, *Souvenir*, *Amulet* or *Annual*, gave the motive for the production of some of the most charming of the engraved work of the fifty years between 1780 and 1830.

It is of the illustration of these little books I am about to speak. Before, however, I do so, you will pardon me if I assume that possibly there may be present a few to whom the art of engraving, as it must be understood in this application of its several methods, may not be entirely familiar, and I will very shortly indicate the methods which at the moment most interest us.

Some of you have probably seen in the Museum of Antiquities in the Louvre that wonderful specimen of engraving upon which is recorded in Phœnician characters the account of some of the conquests of a king of Moab 3,000 years ago, and all of us are familiar with the small pieces of copper on which fashion prescribes that our names shall be inscribed by the engraver to be used in the production of the visiting-card of to-day.

Now it is a very wide step between the Moabite stone and a visiting-card, but there is yet a broad identity between them as to the method by which their markings are produced, for both are incised, the rough chisel on the basaltic stone of Moab finding its exact counterpart in the more delicate graver of the card-plate. Both, then, are incised, that is, the level surface is cut by incision, and both are in intaglio. I will return to the familiar card-plate, and let it serve me in illustration. You see in such a plate that the character, in imitation of writing or of some variety of type, has been sunk below the surface. If a suitably prepared stiff ink is rubbed over the surface in such a way that the sunken hollows of the plate become charged with it, and then that surface is cleaned or cleared of the ink upon it, the hollows alone remain filled with the ink; the plate thus charged being placed under the rollers of the copperplate press with the sheet of paper or card which it is desired to print in immediate contact with it, the ink in the hollows of the plate is given off to the paper, and we have then what is technically called a "print." The process is precisely the same whether the plate be a common card-plate or an etching by Rembrandt.

I have spoken so far of the incised work as produced by the graver, which is, in effect, a finely-pointed chisel; there is, however, another method by which the incised work is produced on the plate, namely, by the erosion of the metal surface, be it copper or steel, by aquafortis. In this case the plate is coated with a thin film of varnish, upon that film the engraver draws the design with a fine needle, the needle cutting through the film and laying bare the metal beneath; the plate is then subjected to the action of aquafortis, which in all the exposed lines bites into the metal, and in this way plays the part which, in the other case, is taken by the graver. This is crudely put, but I hope it is sufficient to convey to you a general idea of the operations.

On the screen you will now see an example of the result of each of these methods. The first is "*The Young Novice*," engraved by Greatbatch after a picture by Northcote, and the work is entirely that of the graver; and the second is after Turner's "*Greenwich Hospital*," engraved by William Finden; with the exception of a few lines on the boat and the figure in the foreground, this is all etched, that is, the lines are formed by the action of aquafortis alone. This is, of course, an impres-

\* A paper by Mr. George Chulow, read before the Applied Art Section of the Society of Arts on May 11.

sion from the first state, as it is called, of the plate, pulled for the purpose of the engraver, and in its completed state, as you now see it, is worked upon by the graver. I shall have occasion to refer to both of these again.

It seems to me that of all the arts which have sprung from that of design, there is none except architecture and painting which has given pleasure to so many or has been of so much benefit in shaping correct ideas as to form and of educating the eye and the intellect as that of engraving, whether on metal or on wood, though with the latter we have nothing to do to-night. By means of the burin of the engraver we have had brought within the immediate reach of nearly everyone the best work of the artists of all countries and periods, and it has served in many cases to preserve to us priceless designs which would have been otherwise lost. Very much of the work of the great artists of three centuries ago exists only now by the copies made contemporaneously by the engraver. Engraving, moreover, has proved to literature and the right understanding of it an aid which entitles it to take rank with literature itself. John Evelyn most happily speaks of a picture, and he had in his mind an engraved picture, as a kind of universal language, for he says that "although it has no tongue it can yet speak and convey instruction"; how true this is we know by our everyday experience.

Although I claim for England the possession of a distinct school of engravers, worthy in their way to be called "little masters" as much as the "little masters" of Germany of an earlier period, I admit that we cannot be said to have had a school of engraving before the middle of the last century. We had, however, a hundred years earlier a few able and distinguished men who as engravers have left a broad mark for themselves; I need only mention Elstracke, Delaram, Faithorne and Hollar, and later the names of Hogarth, Woollett, Strange and Sharpe occur naturally to us. Of the brilliant cluster of engravers in mezzotint of the last century we have no concern at the moment, tempting as it is to speak of them; what the fame of Sir Joshua Reynolds, for example, owes to such engravers as McArdell, Houston, Fisher, Grozer, Valentine Green, Pether and others is known to us all.

But I am being tempted into the broad fields and out of the path upon which I have set out, for it is with the illustration of books by the "little masters" of whom I have spoken that I have to deal. Prior to the last quarter of the eighteenth century the illustration of books had been confined for the most part to the delineation, with more or less accuracy—generally considerably less, I apprehend—of the features of historical personages, or the subjects of biography and archaic representations of historical events, but there had been little attempt to create the actual circumstance and incident of the novelist, poet or historian in a realistic way. The books which are in my mind as marking a distinct epoch in the art of illustration by engraved plates appeared in 1780 as the *Novelist's Magazine*, which seemed to suddenly focus within its pages a new school of artists and engravers in line, the name which stands out the most prominently among the artists of that period being that of Stothard, and those of James Heath, Sharpe, Goodall and Finden among the engravers. A fashion was set, and a pretty fashion it was, and able and accomplished craftsmen were found to give it ample expression; such men as the Heaths, the Findens, Neagle, Noble, Fittler, Freeman, Ridley and Bartolozzi gave us things of beauty in constant succession. I do not attempt to give a catalogue of names of all the clever engravers who were occupied upon the book illustration of that period, but I know that I am finding for you a wide source of enjoyment in indicating so much as will induce you to seek further for yourselves. I have selected Stothard as an artist to serve as a kind of text, because he was perhaps the designer most in demand by the publisher, and whose work passed into the hands of the largest number of engravers for reproduction. I want to be, nevertheless, understood as not selecting Stothard because his work was uniformly better than his *confrères*, because there were others, and notably Westall, who, less prolific, attained a high average of artistic excellence, but there is an almost constant charm about all that Stothard did, and we linger admiringly over the exquisite grace and proportion of most of his compositions, the tenderness of his invention, the charm of his line and the propriety of his accessories. Nothing in English art excels his children and young girls, and he is alike a master in depicting an English cottager child and the *belle dame* of society. Let us stay for a moment and look at the examples which I have selected in illustration of this.

As was Sir Joshua Reynolds with the mezzotint engravers so was Stothard fortunate in finding men to engrave his designs who were in fine artistic touch and feeling with him, men, indeed, who would seem to have found their gravers inspired by the grace and beauty of his design. It is almost invidious to discriminate among such names as Allen, Fox, Humphreys, Goodall, Goodyear, the Heaths and the Brothers Finden, all of them so excellent. On the screen you will see examples of their work, among others, and I may safely leave you to form a competent opinion of their relative merits. I want you, how-

ever, to bear in mind that the examples I have selected for you appeal to me as representative of the highest attainment of this art of engraving "in little," which is to me so impressive and interesting, but do not forget that outside of them are hundreds of examples full of beauty and as good in interest artistically and technically.

I would also have you keep in mind that as you see these engravings on the screen they are enlarged to from forty to sixty times the height of the originals, and that some of them only an inch high are seen on the screen enlarged to 6 feet, because it is on this point of scale that I desire you to share with me the admiration of the consummate draughtsmanship of the engravers, who, without contemplating the severe ordeal which their works thus undergoes, prove the claim good, which I make for them, as being very much more than mechanical reproductions of the original work of the designer. The artist worked, of course, to the scale of the intended reproduction—it was long before the days of photography and its resultant and often abominable processes—and one is frequently impressed by the fact that the engraver has seen and has had the ability to correct the small shortcomings of the artist. I do not intend by this to disparage the very beautiful work in miniature, for such it is, which was created by such men as Stothard, Lawrence, Burney, Westall and others; it would be rank heresy, perhaps, to suggest that Turner could have been improved by his engraver, but I will venture to say that even he had no reason to complain of the interpretation which his compositions received at the hands of the artist-engraver. I wish that it had been possible to have placed side by side the original and its engraving, but I can only now put before you the examples which are selected in illustration of what I have said.

The screen has now on it one of the illustrations to Rogers's "Poems" by Stothard, engraved by William Finden. It is an early working proof and it shows the early stages of the etched and also of the engraved line, and well indicates how the landscape portions are laid in with the etching needle and the figures by the graver. It is followed by a finished proof of the same subject and shows how the lines are deepened, crossed and interlined to produce varying degrees of the shadow and of tone, variations in intensity, which give what is described as "colour." In the next we see the use of stipple. Here let me remark that I do not exclude the dot or stipple as an adjunct to the line, for with it we have an aid to modelling and colour.

"Children on the Seashore," engraved by J. H. Robinson, after Stothard, which I take as an example of extreme freedom in laying in the line and figures—nothing laboured, but every line telling and giving its proper value in colour and tone—it is beautiful in its expression; note the expectant eagerness of the child in arms and the kneeling child.

An example of Charles Heath, after Corbould, excellent in the simple treatment of the engraved line, as seen in the wavelets in the immediate foreground.

Bust of Homer, from the Du Roveray edition of Pope's "Homer" published in 1805. Designed by Burney and engraved by Schiavonetti; the bust and figures in the frieze are all done with the graver, the rest is etched.

Here is a charming illustration after Sir Thomas Lawrence, by Thompson, lovely in pose and modelling, and suggesting the inspiration of the engraver by the exquisite drawing of the original.

"The Embarkation," a subject treated after the manner of Turner, by Whichelo, and engraved by Robert Brandard, who was painter as well as engraver. This is one of his earliest plates. The slide is from a not very good impression, but it serves to show how well the abundance of small detail bears enlargement. In this plate the lines have been laid in by etching, as in the Greenwich plate after Turner, and afterwards re-entered with the graver and the shadows and the darker tones re-bitten.

"Cleopatra Embarking," after Danby by Goodall. I have selected this as similar in subject to the last, and as showing a different handling, but similar mastery of small detail; the method is much the same, but it is not seen at its best owing to the impression not being a good one.

The Medici Vase and a Bacchanalian Vase, both are from Rogers's "Poems," designed by Stothard and engraved by Allen. You will observe the even quality of line on both, a compound of etching, crossed and intersected with fine graver cuts; the careful exactness of work should be noted, the height of the figures in the Bacchanalian Vase being only a quarter of an inch.

Here again is Stothard in one of the illustrations to Walton's "Angler," engraved by Finden. It is a good specimen of mixed etched and graver work, the landscape, grass and foliage being all bitten, and the figures all graver—the grass in the foreground is interlined with fine graver cuts to give harmony and quiet tone; the size of the original is under 2 inches, and the tallest figure less than an inch. Note the head of the elder woman, which is full of expression, though in the original only an eighth of an inch in size.

"Pilgrim and Group of Young Girls" now on the screen is another of the Stothard illustrations to Rogers's "Poems," and is a fine example of William Finden's smaller work. The whole of the figures are in pure line, the grass is etched, the shadows in the grass being deepened with the graver; in the original the figure of the pilgrim is a little more than an inch high, the faces are less than an eighth of an inch.

"The Travelling Musicians" is another of William Finden's plates, the whole of the figures being graver work; the features have extremely fine dots to give small shadows. Can anything be more exquisite in expression than the face of the musician and the upturned face to the left?

"Cora"—a group of amoretti surrounding the figure of the young girl—is another of William Finden's plates after Stothard. The whole height of this is but  $1\frac{3}{4}$  inches.

Here is another of the smaller plates after Stothard, but engraved by Goodall, "The Waterfall," in mixed etching and graver line. Notice the extreme delicacy of the background; as a piece of miniature engraving it would be difficult to surpass. We have here another engraver after Stothard—Shenton—less prolific than most of his contemporaries, but with wonderful vigour and force in his line. In this example—which, without being quite sure of it, I will call an illustration to the "Babes in the Wood"—the horses and figures are fine graver work, intelligent and with a keen perception of colour; the landscape and sky are etched—probably a little overdone if brilliancy is sought—but the whole composition is harmonious and very pleasing.

On the next two slides we have two other engravers after Stothard, both displaying the same delicacy in handling of small subjects and minute figure-work.

The "Death of Raphael," by J. H. Robinson, who was Associate engraver of the Royal Academy. Notice the beautiful liquid flow of the graver lines on the figures throughout; all the figures are very small, the whole composition being less than  $2\frac{1}{2}$  inches high.

"Taking the Veil," by Humphreys. Here the figures are all graver, the rest etched; the line in some parts of the draperies is a little harsh and metallic, but as a whole it is a fine print.

"The Young Novice," engraved by Greatbatch, after Northcote, now on the screen and which we have seen before, is all graver. The open book with the fine lines of writing is but three-quarters of an inch high, and is a *tour de force* of manipulative skill with the graver. The value of gradated line is very effectively seen all through this plate.

"The Fairy of the Lake," after Richter, by Edward Finden. In this plate great brilliancy is given to the figure by the extreme closeness of line in the landscape; the graver work, especially in the hair, is very fine.

"The Vintage," after Stothard, engraved by Goodyear. In this plate brilliancy is obtained by closeness of background in contrast with the high lights in the figures; there is remarkable quality in the engraving of the head of central figure.

"Capture of the Wild Boar." We have here a similar effect gained by fine stippling over the figures, drapery and cloud; the effect is delicate and has great charm, but does not compare well with the results obtained by direct line.

"Girl with Basket." We have here another example of brilliant effect gained by contrast, though in this instance at the expense of some truth, the etched background being throughout too massive and dark.

This example engraved by Chevalier, the figures being all graver and the landscape etched, avoids the fault of the preceding plate, while it is not less brilliant and is altogether more harmonious.

Here is a plate engraved by mixed methods—etching, graver line and stipple—portions of the figures and background being by the latter method; it is shown as an illustration of styles, but is the least good of the series.

"Mary Queen of Scots," by Fox, nearly all graver, the darker parts bitten and afterwards gone over with the graver.

This is a plate by Davenport, which is shown as worthy of a place with the work of the better-known engravers with which it is in company. It is combined etching and graving, and has a pleasing and harmonious effect.

I now return to examples from Stothard—the temptation has been not to leave him—and here we have his conception of "The Poet," engraved by Charles Heath. The figure and drapery are all done by the graver, while the background and accessories are etched, crossed with fine graver lines. For so small a subject there is wonderful strength all through, and on the screen it has the effect of an engraving originally of large size.

"The Dance," engraved by Fox. This is the smallest in size of the examples which you have seen to-night, and despite some trifling exaggeration of details, it is the one which marks, to my mind very emphatically, the claim of these "engravers in little" to a cleverly trained and skilled draughtsmanship. The original is exactly an inch high; the figures are all by the graver, the rest etched.

Next we have two subjects engraved by William Finden. Note the great simplicity and freedom in arrangement of lines, and in this single figure the accurate drawing and sense of motion which it conveys.

We have now four landscape studies, all engraved by Finden, after Turner. To me they seem marvellous in their subtle expression of colour and of size, although the originals are none of them more than 2 inches high.

A pretty composition—a domestic group—again by Stothard, and engraved by William Finden. The graver and etched work are together here in most happy and effective conjunction.

With the four friezes after Stothard, also engraved by William Finden, the illustrations end. Of their claims as compositions I need not, I feel, speak; of their beauty and grace you are able to decide, and as examples of the masterly union of the etching needle and the graver, it is not, I conceive, possible to find finer examples among the group of artist engravers which I have so imperfectly reviewed, or, indeed, among the engravers of any time or country. I hope that I may, however, have, to some at least, directed attention to a branch of the beautiful art of engraving which has not been fully explored, and which has in it a source of great artistic gratification.

What the outlook for the engraver is nowadays I cannot say. It would seem as if it was a case, not of there being no longer men able to produce such work, but rather that they have been starved out of existence. We can only look regretfully at the fact that an art so charming has all but died out with us, and hope that some turn of the tide of demand may again bring it into vigorous life.

## PLUMBING AND SANITARY WORK.\*

ON one of the dog-days in July of last year, when everything was in a state of dissolution, I received a letter from the honorary secretaries of this Association asking me to read a paper on "Sanitary Plumbers' Work and Sanitation," and being in a melting mood, and it being "the second time of asking," I flowed out naturally enough into so pleasant a channel, and accepted the honour. And if since then I have had many qualms about so fluidal a condition, they have arisen chiefly from the fear of being unable to interest so important a body of gentlemen as the Architectural Association, and so to-night, in a more apprehensive state of mind, I crave your indulgence.

The subject is too large and the time too short to admit of any adornment, even if I had the power, but in this I am not troubled, knowing well enough how learned you all are in the art of embellishment, and that any deficiency of mine in this respect will readily enough be made good by you.

Holding the strings of his client's purse, money naturally becomes an important factor with the architect. He ever wants to accomplish so much for so little, and somehow money does not increase in value as the years go by—the wages world makes a shrinkage in it. I should like, therefore, to comfort your minds at the outset by saying—speaking obviously apart from the increase in plumbers' wages, which applies to all the other building trades—that the sanitary plumbers' work of to-day costs but little more relatively than did the insanitary work of two or three decades ago.

The additional cost for better treatment and arrangement for better ventilation of the soil-pipes and waste-pipes is largely met by the adoption of more simple methods, by the use of cheaper traps, smaller waste-pipes and soil-pipes; also by the use of fewer cisterns and cisterns of smaller size and of a less expensive character; and, further, by the difference in the market price of materials, lead especially being much cheaper now than it was a quarter of a century ago. I will give you an instance by throwing upon the screen illustrations showing the insanitary method of treating a valve-closet thirty to forty years ago, and the sanitary method as generally practised to-day by those proficient in the craft of plumbers' work. The excess of work is so marked in the old method that I need not go into figures to show its greater cost.

No doubt the many improvements which have been made in the best kinds of valve-closets have increased their cost, but this is met by the simplification of certain parts, and by the use of plainer basins, a simple white satisfying for most places now; for we no longer require to study colours in our water-closets—we have our art schools for that—nor do we now seek for closet-basins with looking-glass bottoms.

I think I ought to say that there are older methods of treating the valve-closet than the one just shown, that being considered (half a century ago) an improvement upon the treatment it first received in the latter part of the last century and the earlier part of this. For instance, in the illustration just

\* A paper read before the Architectural Association by Mr. S. S. Hellyer on May 21.

shown the waste-pipe from the safe is trapped independently of the closet-trap, a weeping-pipe from the closet service is turned into it for charging the trap with water every time the closet is used; whereas in the earlier method the waste-pipe from the safe was connected with the closet-trap, as in fact was also the waste-pipe from the cistern. In the earliest method of all these two latter dangers were non-existent: the closets having no safes under them no waste-pipes were required; and as the water was generally pumped up into the closet cisterns where situated above the basements there was no such need for cistern wastes, especially as the water instead of overflowing the cistern could run away through the pipe of the service-box into the closet basin, and through the overflow-pipe of the latter into the closet-trap and out into the soil-pipe. In an illustration later on we shall see how this was done. But I am departing from my subject.

In the old method the Bramah-closet was supplied by means of a spring-valve, a spoon or shoe-valve, or a round drop-valve soldered to a lead service-box, the latter kind being the one just shown; but such details do not in any way upset our conclusions as to the greater amount of labour involved in the old method than in the new.

That carries us a long way, for it mattered not whether a valve-closet or a pan-closet were adopted; the plumber's work was just the same in both, the service box only being a little larger in the former case than in the latter. For good houses the best plumbers used to consider the Bramah-closet the proper kind for the principal water-closets, and the pan-closet for more common use and for servants' use indoors, and sometimes also for the upper servants' use in the yard or area, though the water-closet in the latter places was generally fitted with the well-known long hopper-closet. I will say nothing about the cost of the latter, excepting to remind you that it was cheap and advertising; but I do not hesitate to say that the insanitary pan-closet, with its D-trap and other belongings, cost more than the sanitary pedestal wash-down closets of to-day.

In this reference to the relative cost of the modern method of plumbers' work with that of the old, I am not, of course, taking into consideration the additional comforts and luxuries, if I may so call them—elaborate baths and luxurious lavatories. If people want sitz, spray and shower-baths they must expect to pay for them, as they do for their motor-cars and bicycles. However, I should be sorry to convey the impression that because the prices of certain materials have been reduced, and the work to certain water-closets simplified, that plumbers' work now costs next to nothing; for there is a very important factor yet to be considered, viz. the labour, the crux which generally baffles the best of estimators. Plumbers' wages in London are at the rate of about one-fifth more than they were a quarter of a century ago, and I should think four-fifths more than when the Queen began to reign. The men do not receive this amount of increase in their weekly wage, for they do not work so many hours now. I am saying nothing against this advance in wages. Intelligent, industrious labour should be properly paid for.

The first great requisite in a house is its water-supply, for, in my opinion, as I said twenty years ago, no house can be considered safe to live in which is supplied with unwholesome water. If it were possible to get at the actual facts, it would often be found that many a case of illness and death arose from bad water rather than from bad drains, from water supplied in an impure state, or which had been allowed to become contaminated in its storage. Therefore, when water has to be stored great care should be taken to see that it cannot be rendered impure by its surroundings, cannot be contaminated by the effluvia from water-closets, the emanations from ventilating-pipes, soil-pipes and drains, or from the vitiated air of bedrooms and living-rooms. One hardly expected to have required any further restrictions, but our accountant actually saw two hobbledehois bathing in a cistern the other day. The illustration before you faithfully represents what (I fancied from his face when he told me) amused him as much as astonished him. A proper cistern-room should be provided with lights and openings to and from the external air, and the cisterns should be so arranged that they may be readily and periodically cleansed. For this latter purpose—in addition to any overflowing pipe required by the water company—a cleansing waste-pipe should be so fixed that the cistern, or cisterns, may not only be emptied, but rinsed out with clean water from the ball-valve. To prevent the possibility of such pipes becoming conductors of bad air to the cisterns, great care should be taken to see that their discharging ends are kept well away from open traps, sinks, gullies and places where foul air could enter them. It ought to be superfluous to say this after so much has been written on the matter, but only very recently I came upon an error of the kind we are now considering in a nobleman's mansion, the work having been done but a year or two ago. I will show it upon the screen. The cistern-waste is taken into the head of a long length of 3-inch cast-iron pipe, which, at the time I saw it, was in a very foul state, receiving, as it did, the discharges from

a general sink. That the waste-pipe from the sink would become fouled was pretty well understood by the authorities, for it was trapped rightly enough, though it was not ventilated; but neither the cistern-waste nor the overflow-pipe from the bath had any trap in them, although they delivered into the same head as the sink-waste. Of course trapping these pipes would be of no value, for there would be no water passing through them to keep the traps charged. I could add to such examples and give others of a more serious kind. We shall see some instances of how the cistern water can be contaminated later on in connection with other matters; but I must pass on to consider the important method of supplying cisterns with water.

Apart from the great saving in cost by having a constant supply instead of an intermittent, enabling, as it does, the use of smaller rising mains and cisterns of a smaller size and fewer in number, there is the great advantage of keeping the communication-pipes from the companies' mains always charged with water, and thus preventing them from becoming communication-pipes in another sense—from becoming, in fact, air tubes or passages for communicating disease germs.

In the case of an intermittent supply under favourable circumstances, directly the water is turned off from the main in the street the lower cisterns on the system would be supplied as they were drawn from by the water left in the mains, and it requires no great effort of one's imagination to conceive of streets sufficiently sloping for such pipes to be quickly emptied, and to remain so daily for perhaps twenty hours out of the twenty-four. In such cases—the rising mains in large houses being often of 1½-inch bore, and even larger—the air, infected or otherwise, would pass at times even through such restricted passages from one part of a house to another, and also from one house to another under favourable circumstances.

As the water subsided in the communication-pipes air would enter them through the open ball-valves, nature abhorring a vacuum. And the air which would be thus sucked into the pipes would come, of course, from the air which surrounded the cisterns, and where such cisterns were in open contact with the air from bedrooms and water-closets, as shown on the screen, which represents a suburban house, of which there are perhaps hundreds like it, it could hardly be pure and might be dangerous. The upper cistern is practically quite open to the bedroom, for a badly-fitted door would be no barrier and the lower cistern is not only exposed to the air of the scullery but also to the water-closet which opens into the scullery. No doubt any air-currents set up through the empty main in the street and the communication-pipes to the houses would be induced by the difference in the temperature of the different houses, one house being often much warmer than another.

Fortunately there is a redeeming point in most things, and notwithstanding that specifications direct that rising-mains shall be laid in a manner to empty themselves, they are not often so treated; circumstances intervene and "the best laid schemes o' mice and men gang aft agley;" the street main, for instance, stands higher than the point of ascension of the rising-main. But in cases where houses stand on much higher levels than the street main no doubt such communication-pipes would empty back into the main in the street or road, and in streets or roads with a steep fall, as shown, the main with the water turned off would soon become empty.

With a constant supply the main and the communication-pipes would practically remain always charged with water, and no such risk as we have been considering would be likely to take place.

Cisterns with a constant supply can be of much smaller size than when the supply is intermittent; and generally one cistern in such cases suffices for a house with a fair-sized family. The size, of course, must depend upon circumstances. It should be equal to the keeping of all the services from it going at one time, or the service-pipe to it must be of a bore sufficiently large to supply the water at about the same speed that it can be drawn from the cistern.

Where there is only one cistern in a house, and it is also made to supply the hot-water circulation, the cold-water services from it for all other purposes should be so connected that a body of water is always retained in the cistern to keep the hot-water system going in case the water should be turned off from the main for a little while; especially should this be the case when the hot-water circulation is on the tank system.

Also with a constant supply there is the further advantage of being able so to draw directly from the company's main, and the water supplied to the table in this way will be found to be much cooler and nicer in every way, provided that the water in the company's main is pure and wholesome. For this purpose ½-inch lead pipe will be found to be quite large enough. When the water is soft, and would be likely to act on lead, block-tin, or tin-lined lead pipe should be used, or tin-lined wrought-iron pipe if the water company will allow it.

Where the water would act on lead it would also act on galvanised iron; therefore the storage cisterns in such cases should be of cast-iron or wrought-iron limewhited inside, and

the cisterns for storing water for dietetic purposes would be nicer in earthenware, white enamelled inside.

Great care is required in selecting the course for the service-pipe—the communication-pipe from the company's main. The pipe should never be laid under or near a soil drain, or in any trench in which bad or surface water could collect, for even though there may never be any restriction in the pipe to allow water surrounding it to be sucked into it, in case of any hole or defect in the pipe such water may find its way into it when the water is turned off from the main and be forced up into the cisterns when the water is turned on again.

Where such pipes cannot be kept at least 2 feet under ground, then, in positions where they would be liable to very severe frost, they should be laid in a trough or box made of creosoted wood filled up to the top edges of the sides with hot pitch, with which might be mixed a little Stockholm tar and some sharp sand. No lead or iron pipe should be allowed to come in contact with lime, and when such pipes pass through clay soil they should be well tarred over or be embedded in ashes or cocoanut fibre, which will also be helpful in protecting them from frost.

If plumbers' work inside our houses ended here we should not have much to fear from noxious gases in our homes, but civilisation calls for certain conveniences to be placed indoors, and I must confess that it is most comforting to one's mind, if feeling a little "out of sorts" on going to bed, to know that if taken ill one will not have to light a lantern as in the olden times and go out into the night air.

Now I know of no reason beyond that of incapacity why a water-closet should not be fixed inside a house with absolute safety, safer and sweeter, in fact, than in a night stool in one's bedroom, the use of which, when all the servants are in bed, would leave its presence painfully present for the rest of the night. But it is not so much a question of a night-stool versus a water-closet, or a privy or water-closet situated out of doors versus a water-closet indoors; for the outside convenience, by bad arrangement, may render it and the air surrounding the house more unhealthy than even an insanitary water-closet indoors. The important question is, Can a water-closet be so fitted up that it can be used with absolute safety in any position or place it may reasonably be required, either outside or inside a house? Well, gentlemen, if I could not answer that question in the affirmative, I should not be here to-night.

Living on an island, we naturally believe in isolation. We isolate all clean water pipes such as safe-wastes, cistern-wastes and overflow pipes by making them discharge into the open air. We also isolate all dirty water waste-pipes, such as bath wastes, sink wastes and lavatory wastes, by exposing their discharging ends to the air outside the house, and in this matter we stand ahead of all other nations, not excepting even America. In some cases we also isolate soil-pipes by "disconnecting" them from old and filthy soil drains, safeguarding them from the air in the drain, and giving to each soil-pipe a separate inlet and outlet for continuous ventilation.

We go further than this, for we not only isolate the drain of one house from that of another, by disconnecting both from the common sewer, but in some cases we disconnect one section or wing of a building from that of another, excluding any infected air which may be in one section from another, and providing independent ventilation to each section, taking care, however, that no length of drain shall remain unventilated.

And we not only isolate the main carriers, the sanitary wings are now isolated from the general building. And the water-closet apartments are not only isolated, but the water-closets. The "Corbel" and the "Bracket" closets have been specially introduced to isolate them from the floor as well as from the walls, an illustration of which is now before you.

But isolation is not everything; our ships of war still count for something. A water-closet may be as isolated as a sentry-box and yet be dangerous, for in this sanitary age no water-closet can be pronounced sanitary in the highest degree which cannot be used and left in itself and in all its parts as clean and wholesome as it was before usage.

To compare various points and features of the great variety of water-closets and flushing-cisterns which now exist would require several evenings, and to attempt this to-night would only tend to the confusion of our minds on a subject simple enough in itself, but which, owing to the multifarious patterns of the many manufacturers, has become a little complicated.

In passing over many water-closets which have been introduced during the last ten or twenty years we shall not miss much, for the majority of them are as noisy and as unsightly as some of the new motor-cars, and to the olfactory nerves are just as objectionable as the pan-closet they were meant to supersede. I propose, therefore, to confine my remarks to a few kinds, viz. the valve-closet, the "Syphonic," the "Wash-down," and the "Wash-out," but before doing so let me mention the several points which I consider essential to a good water-closet.

1. It should hold a body of water large enough and deep enough to quite submerge the fæces.

2. It should have no parts or places in it where fæcal matters could cling to or accumulate upon.

3. It should have a water-seal of at least 1½-inch for trapping off the soil-pipe.

4. It should be so constructed that the whole of its contents may be changed by a flush of two gallons of water, and its interior parts well washed.

5. And in the case of earthenware closets having their basin and trap in one piece, its connection with the soil-pipe or drains should be readily seen.

Now if we examine the general kind of "wash-out" closets, we shall see that they all more or less fail in some one or more of these important points. In the majority of such closets, if not in all of them, it will be found that the water held in the bottom of the basin is too shallow to cover the fæces, the consequence being that the portion which is not submerged throws off a vapour—its temperature being generally greatly higher than the air of the apartment—which soon fills the place with an odour, objectionable to the then occupier, and most repulsive to the next comer immediately following. So pronounced is this, that on making an examination it is rarely necessary for a sanitarian to do more than put his head into an apartment where this kind of closet is fixed to know that it is a "wash-out."

Then in this kind of closet the flush of water is made to break up the fæces in the best possible way for throwing their odours into the apartment, and instead of spending its full force upon the sides of the basin and upon the trap, it is chiefly spent in clearing the bottom of the basin. There is also the evil of a large exposed surface between the weir of the basin and the water-seal of the trap, a part which will generally be found to be in a filthy state.

Having dismissed the "wash-out" kind of closet, let us now see what can be said for its next-of-kin, the pedestal "wash-down" kind. There is a very great variety of them with several points common to them all, and yet they differ so much in certain essential features that, like Jeremiah's figs, "the good are very good indeed, the rest are not fit for pigs." In one particular they all stand at a disadvantage with the "wash-out," viz. that their exposed surface of water is smaller. But the best of their kind may be said to pretty well embody the points required in a good general sanitary water-closet. They are to be had of many a manufacturer, each one claiming some feature or advantage not possessed by others.

In the example before you my assistant will soil over the whole of its interior exposed surface, and will test it with a dozen pieces of paper, using only two gallons of water, and you will see that the closet and trap will be left free of the matters put into them. And as it is more difficult sometimes with such closets to wash out a few pieces of paper of the size of postage stamps, he will try it again and show you that the closet stands both tests equally well.

Several varieties of "syphonic" closets are now in the market, the main object with them all being to provide a larger exposed surface of water than can be given to the "wash-down" kind; but though such closets excel the "wash-down" closets in this particular, they are not so satisfactory in some other points. The majority are not so simple, nor so reliable in their action with only a two-gallon flush of water, and some of them are complicated in their supply and discharge arrangements.

In testing such closets with a pailful of water emptied quickly into them, I have seen them left with a much reduced water-seal even when they have not been attached to a soil-pipe; and how they would withstand the action of syphonage when fixed in about the middle part of a stack of soil-pipe 80 to 100 feet high, I should hardly like to say, but I should be apprehensive of the result.

I know of an instance where a syphonic closet was put into use during the time its soil-pipe was under a smoke test, and the smoke escaped through it into the water-closet apartment. But, perhaps, this is hardly to be wondered at, for under certain conditions the contents of the closet are syphoned out very vigorously, so much so that the water-seal of the trap would often be broken in the action.

The emptying of a pailful of slops into such closets not only syphons out their previous contents, but the added slops as well, leaving the basins practically empty, in which state they would at times be used when the fæces would fall upon dry basins; for, no doubt, the servants would not always remember to pull the flushing handle after emptying the slops, especially as there would be no necessity to do so to get rid of the slops.

Then, unlike a valve-closet, the water held in the basin is in continuous contact with the air in the soil-pipe, but this is the same in "wash-down" closets.

Then I think when the water is limited to 2 gallons it is important that the whole of such a flush should be utilised for washing down the walls of the basin and cleansing the trap; but in the majority of the syphonic closets it will be found that part of the flush is used for starting the syphon in a compartment outside the basin.

Then a close examination of the majority of such closets

when in action will show that their sides are not properly rinsed, and that in consequence particles of matter are left adhering to the surfaces, and that even some of the rinsed water is returned back into the closet when the syphonic action has been broken. But of course a second flush would make this all right. It is better that such closets should have a flush of not less than three gallons.

Before I pass away from the classes of water-closets which may, and which often are, connected to soil-pipes and drains by imperfect joints, I should like to say as strongly as I can that no closet or trap having a breakable outlet, such as earthenware, should be connected to a soil-pipe or drain in a manner that will not admit of a ready inspection.

(To be continued.)

### MEMORIALS OF GREATER LONDON.

THE committee for the survey of the memorials of Greater London, of which the late Lord Leighton was president, and whose members include Lord Meath, Lord Tredegar, Lord Carlingford, the Hon. Lyulph Stanley, Sir Walter Besant, Mr. Hamo Thornycroft, R.A., Mr. Frampton, A.R.A., Mr. E. W. Mountford, Professor J. W. Hales, Mr. F. D. Mocatta, Mr. Humphry Ward and Mr. C. R. Ashbee, has just issued a report of its progress for the last two years. The object of the committee has been "to take up certain areas in London, and in them to register and record with drawings, photographs and other records whatever may be deemed to be of historic or æsthetic interest. The work is not confined to buildings only; any valuable open space, any remnant of an old village green, any beautiful tree, any object of local life or custom that may have a definite external embodiment, or any interesting piece of handicraft, even if it be but a signboard or a wrought-iron gate, comes within the committee's survey. The aim is to draw attention to these things. If they are in private hands, to get the owner's consent towards their registration; if under the guardianship of any representative public or semi-public authority, to encourage their maintenance for public purposes as national trusts." The first publication of the committee was a monograph on the Trinity Hospital in Mile End. Other monographs are in preparation upon the Old Palace of Bromley-by-Bow, Aldgate Church, Hill Hall and the work of John of Padua, Bow Church (Stratford-atte-Bow), the Mile End Road (its external life and character), the Great House at Leyton, Essex House (Bow). Cases are quoted in which the committee have helped to save from destruction notable spots and buildings, and the report says that "perhaps the most successful outcome of the two years' work may be seen in the conference convened last December by the London County Council, and the action resulting from it. . . . How far the identical method of the Council will be subsequently followed by the London County Council, if it should decide to support and continue the work that the committee has set before itself of the registration of the whole of London, it is as yet impossible to say; but acting on the strength of the work already accomplished, the committee invite further support, either by funds or by active assistance, or by gifts of drawings, photographs, or memorials of London as it is." It is mentioned that the next area to be taken up by the committee will be Chelsea. The names of those willing to join the committee either as active or honorary members, or subscriptions to the committee's work, may be sent to the chairman of the committee, or to the secretary, Mr. Ernest Godman, Essex House, Mile End Road, E.

### THE DUBLIN COLLECTION OF ANTIQUITIES.

IN the course of his evidence before the select committee of the House of Commons on museums of the Science and Art Department, Lieutenant-Colonel Plunkett, the director of the Dublin Museum, said that the collection of Irish antiquities was transferred from the Royal Irish Academy to the Dublin Museum about six years ago. He believed one of the conditions was that they should accept the former curator of the collection, Major M'Eniry. He was an old man, and when witness knew him was in bad health, but he did not know him when he was taken over. The collection was unique and one of the finest in the world—finer in some respects than the collections at Stockholm or Copenhagen, or any other archæological collections. He meant more valuable from the antique and artistic points of view, better in every way. Being so valuable and so unique, it was desirable that it should be better exhibited than at present. Of course the gentleman who came over with it being very advanced in years, and for the last year or two in very feeble health, could not have done more than he did in arranging and exhibiting the objects. As regarded publishing the chief objects something had been done, but as regarded the exhibiting and arranging there was an immense deal to do.

An immense number of the objects were stowed away in drawers and out of sight. The post of keeper had been vacant since last November or December, and when they had a keeper and were able to set to work there were two rooms vacant and an immense deal of work for a first-rate skilled archæologist for years to exhibit the collection properly. Sir William Wilde made a catalogue of portions of the collection, and Miss Margaret Stokes had done a great deal towards it. There was no proper catalogue up to date, and nothing was being done in that direction until they got a keeper. The rooms in which the collection was exhibited were among the best in the museum, but the long room, in which alone the public saw it, had deficient light. In the estimates for the current year there was provision for top-lighting it, so he hoped it would be done during this year. He thought they might consider the building fireproof, and of course there were precautions against fire. The safety of the objects against theft was well secured. They proposed to keep the archæological collection apart as one department of the Museum. He thought Major M'Eniry's salary was 257*l.* a year. He was aware that gentlemen in the position of Mr. Skinner and Mr. Weale at South Kensington Museum got a very much larger salary than that, and he thought that unless that salary was materially increased they would find great difficulty in securing a man who would do justice to their wonderful collections. He thought the keepership of the archæological and Irish articles ought to be put on the same footing as the keepership of the art and industrial collection, or the keepership of the natural history collection. The keeper of the art and industrial collection got double the salary of the keeper of the Irish antiquities. Witness was further examined in much detail with a view to the alleged lack of care of gold and other articles in the museum, and as to the charges which had been made of bad arrangement. In witness's opinion Mr. Arthur Evans displayed extraordinary ignorance of art in the letter to the *Times* with regard to the Celtic collections in Dublin. He said it was untrue, as stated in the letter, that "no less than 1,000*l.* of what is nominally an Irish grant was expended in London for the Dublin Museum without any reference to the officials on the Irish side of the water." Nothing was ever purchased without consulting him now, and therefore he was quite sure that nothing was done without consulting his predecessor. When the visitors met to make their annual report they could receive, if they required it, information and advice from witness and from the keepers of the various departments. He had been in his present position one year and five months, previously to which he was secretary of the Royal College of Science. He had the control of everything in the museum. Their staff was very scanty indeed. He had asked for an increase, and he supposed it was the fault of the Treasury that it was not granted. The Treasury objected to making a keepership of the Irish antiquities and giving a salary to a keeper. There were not many men suitable for the position, which required a man who was a comparative archæologist, thoroughly skilled in all modern imitations of archæology, and, also, he must have a very special knowledge of Irish antiquities. He found it very inconvenient to have the keepership of the Irish antiquities vacant, but he would rather have it vacant for twelve months, and then have the right man in, than that an inferior man should be appointed in a hurry. The reason it was vacant so long was that they were trying to get the salary increased by the Treasury. Until it was settled what the salary was to be of course it was impossible to make the post known by advertisement or otherwise. He heard the other day that the Treasury had refused to give what was wanted, but he could not say whether that was absolutely fixed or not.

### TESSERÆ.

#### Llanthony Abbey.

THE remains of the Priory of Llanthony are situated in the Vale of Elwias, surrounded by the Hatterill Hills. The priory owes its origin to one of the followers of Hugh de Laci, who, about the year 1108, being joined by Ervistus, chaplain to Queen Maud, erected a hermitage, which, by valuable endowments, was in a few years raised to the more important establishment of a priory, and Llanthony became the habitation of a fraternity of black canons, who dedicated their church to St. John the Baptist. Circumstances led some of the monks to remove hence to a cell in Gloucestershire, belonging to the priory, as a temporary residence, which, however, proved so agreeable to them that, at a subsequent period, they not only refused to exchange the fertile plains of Gloucestershire for the comparatively barren soil of Elwias, but claimed for their favourite possessions a pre-eminence over the mother church. The few monks left at Llanthony were exposed to oppression and pillage; consequently the establishment declined, and the dilapidation of the buildings commenced. Edward IV. attempted to unite the two establishments by a charter. It is,

however, uncertain whether the projected union took effect, as the two priories were separately valued at the dissolution of the monasteries. Very few views of Llanthony have been published. From its secluded situation it seems to have escaped the notice of the tourist more than any ruin of like importance. The priory church is 208 feet in length inside; the nave, 27 feet wide; the aisles, 9 feet 3 inches, exclusive of the piers; the whole width is 53 feet 6 inches; the length between the north and south extremities of the transepts is 101 feet, and their width the same as the nave. The small passage south of the transept is perfect; its details are of a bold and beautiful character. The chapter-house adjoining is evidently of the same date; the few fragments now remaining are elegant and expressive. The gatehouse to the priory, several hundred yards westward of the church, is a good specimen of the early style, but of later date than many other existing parts of the monastery.

### English Historical Medals.

The first contemporary English medal is of Sir John Kendal in 1480, and of Italian workmanship. We have a gold medal of Henry VIII., date 1545. Evelyn remarks that in this medal Henry appears in his usual bonnet, furred gown and invaluable collar of rubies. The first coronation medal of England is the one of Edward VI.; it is of very indifferent workmanship and in low relief. There are several beautiful medals by Trezzo of Philip and Mary, and many curious ones of Elizabeth on her accession to the crown, and the defeat of the Spanish Armada in 1588. The medals of Elizabeth are generally cast, and have highly raised borders richly embossed; during this reign, too, we have some exquisite medals by the famous Stephens of Holland. It is doubtful whether there are any works superior to them for style in art; the admirable manner in which the flesh is treated in distinction to the hardness of bone in the face could not be sufficiently studied or admired by the medallic artist or amateur; the reverses, however, are not equal to the heads. All the medals by Stephens are exceedingly rare. The history of James I. is tolerably well preserved in medals; they generally, in style, resemble those of Elizabeth; but there is a very good one by Warin, of Sir Thomas Bodley, founder of the Bodleian Library at Oxford. In the early part of the reign of Charles I. we have many counters struck on his marriage. The medals of this monarch are numerous, many of which were engraved during the time of Charles II. by the Roettiers. Cromwell was fortunate in having excellent artists. The two Simons executed all the best medals; Abraham was a modeller, and there still remain in the British Museum many excellent models in wax by him; they were generally cast in silver, and some of the best were left untouched from the casting, but others were admirably chased and repaired by Thomas Simon. The great merit in these works is the characteristic expression of living nature; other artists have been more correct, but often coldly correct, as compared with the Simons. A large oval medal, struck in gold, was presented to Admiral Blake after the engagement with Van Tromp in 1653. Of Charles II. there are several good medals. Many medals occur of James II., both before and after his abdication; and the events of the reign of William III. called forth many interesting medals—the Dutch ones extend even from his infancy. The medals of Queen Anne are not only interesting as works of art, but particularly so as recording the great events with which Marlborough illuminated her reign. About 1730 John Dassier, a native of Geneva, settled in London, and engraved a series of medals of the kings of England. They would be more valuable if the portraits could be relied on. He also executed a set of small medals of the reformers, and commenced a series of our great men. His nephew, James Antony, who on Croker's death was appointed second engraver to the Mint, engraved several others. The character of workmanship of both the Dassiers, notwithstanding their industry and ingenuity, was that of extreme hardness and precision of outline; still there are very clever medals by them, and they evince an advance upon the state of the medallic art of that period.

### The Pointed Arch in Sicily.

The Sicilian Normans employed the Pointed style, and it is supposed they adopted it from the Saracens. How came the Saracens of Sicily by it? Was it invented by them, or for them in Sicily, or did they bring it with them? Sicily at the time of the Saracenic invasion was exclusively occupied, and had for centuries been occupied by the descendants of Greeks and Romans, who, when left to themselves, invariably adhered to as close an imitation of the Roman style as the state of the arts enabled them to accomplish. It was not in Sicily, therefore, that the Pointed arch would be found by the Saracens. Was it invented there? Let us cast a glance over the countries from whence the conquerors came, and see whether in them we shall not find the answer to this question. Sicily was conquered by the Saracens in 832. By that time the Arabs had extended their empire over Persia, Syria, Egypt, Africa proper and Spain, and wherever they went had become great builders. Bagdad,

Fez and Morocco were already splendid cities. Abdalrahman had already built his palace at Cordova, and several hundred mosques had been raised in different parts of the Mohammedan empire. The Arabs, therefore, had already had a considerable practice in architecture, and were likely to have acquired a predilection for some particular forms. Without precise information, as we are, with respect to the style which they habitually employed at that remote period, let us observe what style they did employ at the nearest period to the moment in question of which any monuments exist. The earliest Saracenic buildings of which the date is accurately known, are to be found in Cairo. The Nilometer was rebuilt where it now stands, and as it now appears, by Motawkel, tenth caliph of the Abassides, in 859. The mosque of Teyloun was built in 879, and the mosque of Hakem in 1003. The dates are recorded in Cufic inscriptions still existing in the walls of the buildings, and in all these buildings the Pointed arch appears. In Spain the oldest Saracenic arches, though slightly pointed to the eye, are all on the Pointed principle, that is to say, arches not struck from one centre, like the round arch, but invariably struck from two or more centres. Upon the whole, then, it appears that the Pointed arch came from Africa to Sicily; but how did it find its way, at a later period, into northern France and Germany—the countries of the continent of Europe in which it first made its appearance? We might have expected to have found it first in Normandy, as intercourse was constantly kept up between what may be called the mother country and the Sicilian colony; but the Pointed arch did not appear in Normandy as soon as it appeared in other parts of northern Europe.

### Thomas Stothard.

Stothard, as an inventor in composition, was equal to all, but as a painter was certainly inferior to all. In fact, he could not paint; he had no identity of imitation; he did not, and could not, tell a story by human passions; and his style of design showed great ignorance of the constituent parts of the figure. But there was a beautiful and angelic spirit that breathed on everything he did. He seems in early life to have dreamed of an angel, and to have passed the remainder of his days in trying to endow every figure he designed with something of the sweetness that he had seen in his sleep. It was impossible to be in Stothard's painting-room for ten minutes without being influenced by his angelic mind. He seemed as if he had been born in the wrong planet. He had a son whose etchings from our ancient tombs are an honour to the country. He fell from a great height in pursuing his designs from some tomb in a country church and was killed. This ill-fated artist was in every respect worthy of his father. Never were there four men so essentially different as West, Fuseli, Flaxman and Stothard. Fuseli was, undoubtedly, the man of the largest capacity and the most acquired knowledge; West was an eminent artist in the second rank; Flaxman and Stothard were purer designers than either.

### The Neglect of Greece.

The indifference and ignorance about the actual state of Greece continued to so late a time that, even in the huge quartos of Pinkerton, published at the beginning of this century, the whole country occupies only one page, and Athens is despatched in half a line, from which we learn the important fact that "Atini, the ancient Athens, is of small population." Till the year 1678 Greece was almost as much lost and unknown to Western Europe as Pompeii and Herculaneum. It is true, indeed, that more than two centuries before this time Ciriaco de Pizzicollis, a native of Ancona, had visited the country in search of Greek inscriptions—of which he was such an ardent amateur that, being informed by a fellow-passenger while he was on his voyage homeward of the existence of an ancient marble which had escaped his notice, he immediately left the vessel and went back eighty miles by land to examine it. But the Itinerarium of Ciriaco, containing a brief account of his journeys in Greece and other countries, which he wrote at Florence in the year 1441, remained 300 years in manuscript and was first published at the same city in 1742. We have no account of any travels in Greece during the sixteenth century, and the only document from which we can glean any information concerning the then state of the country is a volume entitled "Turco-Græcia," published at Basil in 1584, and containing a history of the city and church of Constantinople during the fifteenth and sixteenth centuries, written by Greeks residing in that city, with a collection of letters from writers at the same place and of the same nation, addressed to Martin Crusius, a scholar of Melanchthon, and professor of Greek and Latin at Tübingen. One of his correspondents, a native of Nauplia, assures the professor that wisdom, science, arts, learning, valour, wealth and all other good things have departed from Greece, and that the Muses themselves have quitted Helicon and Parnassus and have settled, he supposes, at Tübingen. The same writer reproaches himself for wasting words upon such a wreck as Athens. "Why," says he, "do I

dwell upon the description of this place, which is like the hide of an animal that has been long dead?" From his conversations with another Greek, the professor himself infers that Greece had ceased to exist in Greece and Athens in Athens. These and many other passages of this volume, in which the writers feelingly deplore the degraded and desolate condition of their country, would tend rather to discourage than to invite the curiosity of travellers if the book attracted any notice at the time. But the letters are so dull in style and so barbarous in language that few would be tempted to search for the little information they contain. From 1584 to 1678 we have still only two or three scanty notices of the condition of Greece, and these are so replete with fictions and absurdities that their authors could never have ventured to blunder or to invent with so much boldness if they had not been assured that the ignorance of their contemporaries would secure them from detection.

#### Athenian Houses.

An inherent defect in the construction of houses in Athens occasioned great inconvenience; the stairs were erected in the street, and the upper apartments, projecting over these, disfigured the façades, obstructed the view and prevented a free circulation of air. According to Aristotle all this arose from the avarice of the proprietors, who, by placing galleries over the heads of the passengers, endeavoured as much as possible to gain possession of the very streets. The Areopagites, who had the immediate inspection of all the buildings at Athens, did not, in this point, render their policy severe, and they even pretended to discourage all innovations in domestic architecture. In consequence of this their tribunal had a ceiling of clay only, it was the model proposed for the citizens, and being thus recommended any deviation from it would have been attended with danger. Amongst us, says Euripides, it is a general rule with architects never to adorn the roofs of houses, nor render them at all remarkable. An edifice too highly decorated, or distinguished by a little more than common elevation, must instantly have attracted a crowd of jealous observers; and suggestions would not have been wanting that this ostentation denoted a pride incompatible with republican equality. Those who, from experience, know the spirit of popular or democratic governments, will conceive this without difficulty; but to such as have never had an opportunity of acquiring this knowledge it must appear almost incomprehensible. The Areopagus was a very mysterious tribunal, and conducted by such obscure maxims that its principles could only be unveiled by a perfect acquaintance with all the secrets of the State. This court would never approve the plan of the orator Timarchus, who proposed that the republic should erect a range of buildings along the place called Pnyx, which was allotted for the assemblies of the nation. The Areopagus dreaded to see these new edifices converted into places where the citizens would have been tempted to injure their reason with wine before they came into the public place to discuss affairs of state. Yet this spot was in a state of unexampled desolation and unworthy of the majesty of a people pretending at once to the empire of the sea and the first place on the Continent. Another circumstance tended still further to the deformity of Athens; many spots, according to Xenophon, remained vacant where the habitations had either been destroyed by fire or erased by a decree of the people. No sooner was a citizen accused of high treason or some such crime than immediately his house was demolished, as a vessel is broken which has contained poisonous liquor. Neither was it lawful to rebuild there, for the very ground was supposed to become fatal and execrable from the crimes of its former possessors.

#### Restoring Spanish Paintings.

The greatest care is necessary in cleaning Spanish pictures. A large portion of those now remaining, and which come under the inspection of the purchaser, are dried up and the oil exhausted by exposure to the burning sun, in a climate so favourable to evaporation. It is common to see pictures of which the surface crumbles to dust in the fingers. With those there are two plans to be pursued. The first is to fix the colour, which is done by a species of glue applied to the surface; the picture should then be lined, and the operation of what the Spaniards term giving jugo, sap or juice, be commenced. This consists in applying walnut oil slowly and successively as the picture will absorb it, when it gradually assumes consistency and shows the colours. After this the cleaning may be done, but the picture should if possible be exposed to the air for some time previously. The cleaning is an operation of extreme delicacy. In all the schools, especially in that of Seville, and more particularly in the pictures of Murillo, from some cause, either of the oil, or of the oxidation of the mineral colours of the glazing used to finish, they acquire a dinginess of colour and have often a roughness on the surface from the handling of the master. Both these circumstances try the nerves of picture cleaners and of most of their employers, and a picture is seldom allowed to remain in this

state. Some acid or other method is tried, the patina and the supposed blemish come off together, and the picture is washed, as are nearly all in the galleries. The fine finishing of the master is irretrievably gone and is frequently attempted to be restored by what is called toning. Very few exceptions are seen, either in the works of Velasquez or Murillo, and those of the latter frequently resemble copies, from the faint and cold colours which now form the surface, and which in London is frequently supplied by quantities of varnish, and in Paris by picking away the outline and giving fresh relief or rotundity to the picture, which is thus re-manufactured.

#### Exhibition of Non-Inflammable Decorations.

SIR,—Under the circumstances connected with the recent disastrous fire in Paris, will you permit me to direct attention to the exhibition of fireproof materials made from asbestos to be opened in the large hall of the Society of Architects, St. James's Hall, Piccadilly, at one o'clock on Monday next, the 31st instant?

This exhibition, suggested by the above deplorable event, has been organised in order to demonstrate means of assisting in the prevention of loss of life by the use of non-inflammable decorations in our homes and public buildings.—I am, Sir, your obedient servant,

J. ALFRED FISHER, General Manager.

The United Asbestos Company, Limited,  
Dock House, Billiter Street, London, E.C. :  
May 26, 1897.

#### GENERAL.

**The Prince of Wales** on Wednesday opened the new medical school buildings at Guy's Hospital, which were designed by Mr. J. H. T. Woodd.

**A Commission** has been formed to arrange for the retrospective exhibitions in the great international show at Paris in 1900. It will consist of 200 members, including officials, critics, collectors, &c., with MM. Pol Neveux and Migeon as secretaries.

**Mr. H. Douglas Horsfall** proposes to build and endow a church at Liverpool as a memorial of the Queen's reign.

**The Site** for the new University College Hospital has been secured, and the questions of light and air settled with the adjoining owners. Mr. Alfred Waterhouse has rearranged the plans, so that a much finer entrance is made for the outdoor patients, this being a particular request of Sir Blundell Maple, who is anxious that patients while waiting to see the doctors should be comfortably provided for.

**The Bishop of Capetown** stated on Monday that an energetic attempt is now being made to erect a cathedral for his diocese at a cost of 100,000*l*.

**A Visit** will be paid by the Northern Architectural Association on June 9 to the Leeds Steel Works to view the manufacture of steel, in its various processes, from the ore to the finished girder.

**Plans** have been prepared by Messrs. Cossins, Peacock & Bewlay for the extension of the Deritend branch library, Birmingham.

**The Bill** for the construction of a subway between Greenwich and Blackwall was approved by the Committee of the House of Commons on Wednesday.

**The New Gallery of British Art** at Millbank is rapidly nearing completion, and is expected to be ready for opening in July. Some of the rooms are finished, the walls being hung with tapestry of a deep lake colour, which will form an excellent background for the display of pictures.

**Messrs. Whitelegg & Whittaker**, architects and surveyors of Manchester, notify us that they have removed to larger and more convenient offices at Somerset Buildings, 19 Brazenose Street.

**Mrs. Rutland Barrington** has informed the vestry of St. Mary Abbott's, Kensington, that the sisters of the late Lord Leighton had offered to present to the nation his house and all the treasures in it, provided that suitable arrangements could be made for the acceptance of the gift and the maintenance of the property. The vestry were asked to nominate two or three representatives to attend a conference of authorities interested in the matter. Canon Pennefather (vicar), Major Isaacs and Mr. Fellows-Guy were appointed to attend the conference, the date of which remains to be fixed.

# The Architect.

## THE WEEK.

ONE of the oldest and, as many think, one of the greatest of the French landscape painters died on Friday last in his eighty-second year. FRANÇOIS LOUIS FRANÇAIS was born at Plombières in 1814, and his first experience in Paris was as a bookseller's assistant. From selling books he was inspired to illustrate them, and while still in his teens he obtained a commission from a publisher. He was fortunate in being accepted as a pupil by JEAN GIGOUX. His first picture in the Salon was in the exhibition of 1837. His work was then rather timid in style, but a visit to Italy with COROT worked a revolution with him. One of the effects was the indefinite character which he imparted to the figures in his landscapes. A correspondent of *The Architect*, describing an interview with the painter some years ago, said:—"M. FRANÇAIS expressed his regret that the young school so freely indulged in the reproduction of the costume of the day in its minute details, which, however necessary in a portrait as illustrative of the idiosyncrasy of the sitter, are, in his opinion, out of place in a landscape. 'When a figure enters into a landscape,' said the master, 'the first duty of the painter is to subordinate it to the laws of light, and consequently to treat it as "une valeur de ton, dans l'ensemble." It seems to me,' he continued, 'that the modern school is just now under the influence of Japanese art. The Japanese neither understand the laws of perspective nor gradation of light.'" His *Jardin antique* carried off a third-class medal in 1841; *Sentier dans les blés* won a second-class medal in 1843; while in 1848 his works were deemed worthy of a first-class medal, and consequently of being *hors concours*. M. FRANÇAIS was created Chevalier in 1853, and Officier de la Légion d'Honneur in 1867. In partnership with GERADET, FRANÇAIS undertook the illustration of "La Touraine," one of the most splendid works ever published in Paris. MEISSONIER painted the figures in the *Parc de St. Cloud* (1846). In 1853 FRANÇAIS exhibited *Fin d'Hiver*, purchased by the Government, and which is now at the Luxembourg. Among his most celebrated landscapes, besides those mentioned, are *Vue prise du Bas-Meudon*, purchased by the late Prince JEROME NAPOLEON; *Orphée*, exhibited 1861; *Les Bois*, 1864; *Environs de Rome*, 1866.

MERRY Margate must now be in that happy state when large profits can be anticipated. All the world is coming to London, and, according to the fortunate people who take in visitors, there is no place in England which can so efficiently restore minds and bodies that are tired in the Metropolis as Margate. Are the inhabitants to be blamed if they have golden visions? But the staid members of the School Board are engrossed by cares which would make them indifferent if it were announced that Pactolus was for several months to run into the town and spread its wealth over the sands. They have just erected two schools, and have drawn the final cheque for the architect, Mr. REEVE, but they do not possess his plans of the buildings. The utility to themselves and the ratepayers of two rolls of drawings is not plain, but the want disturbs the members and prevents them from enjoying themselves like the rest of the inhabitants. The cheque was drawn conditionally upon the surrender of the drawings, but the architect still hesitates. There is a clerk, who is a lawyer, and he obeyed the instructions of the Board in informing Mr. REEVE about the condition, but he wisely declines to say whether it is an entirely legal condition or whether the Board have a right to the plans. He was asked whether Mr. REEVE could legally detain the plans or not, and the answer was, "Mr. REEVE has detained them, but if you are going into the legal point of the question, I must ask you to go into committee." When one of the members who was probably a little alarmed about the consequences of the affair subsequently inquired whether the Board could put off the payment of the cheque, the clerk answered:—

"Until somebody has asserted legal rights to obtain it, the Board is perfectly right in withholding it. But a great deal more has been made out of this than was necessary, and it ought to be discussed in private. In no case do I give a legal opinion in public if I can help it." The Lord Chancellor could hardly offer a more prudent remark, and everybody is free to put his own interpretation on it. Our advice would be, Let the Board take no more trouble about the plans, but devote their thoughts to preparations for the coming season and the native, colonial and foreign victims who are to enrich Margate. The plans will not aid in increasing the tributes which will have to be offered, and they would be as useless to the Board teachers and pupils as in the lodging-houses. If the case is to be fought on technicalities of language, we would also recommend Mr. REEVE to put himself in the hands of a lawyer as shrewd as the clerk, if one is to be discovered in Margate. His theory that "author of a plan" means "owner of a plan"—and the use of the phrase by the School Board is evidence of the Board's admission of his right to his plans—is novel, but it would not be wise to rest an action on so ingenious an interpretation. As architects well know, the owner of a plan, although an architect, is not necessarily the author or designer of it, but the owner can hold it and enjoy the rights of authorship in it until it is purchased from him. A lawyer, like the clerk of the Margate School Board, would not advise an assumption of ownership by his clients until all conditions of purchase were fulfilled.

THE works committee of the London School Board have had under consideration the question as to the hours of work of the clerks of works employed by the Board. The existing rule with regard to that section of the clerks of works who are engaged in superintending the erection of schools, enlargements, &c., is that they shall be "in attendance on the works during the whole of the working hours, unless specially relieved from duty or summoned to the office." The committee are of opinion that a similar rule should be passed with regard to the whole of the clerks of works, whether permanent or temporary, who are engaged by the Board. It is therefore proposed that in future the hours of all clerks of works, whether permanent or temporary, employed by the Board be the same as those recognised for workmen in the building trade, it being understood that their attendance will be required at other times, if necessary, while the men are at work.

PRIVATE individuals and companies are not the only sufferers from obstacles to light. Sir A. GEIKIE reports a case which affects the public and government officers, and has led to the waste of public money. After the petrographical and palæontological collections of the survey had with much labour and thought been arranged in the gallery assigned to them in the Dublin Museum of Science and Art, a range of high buildings has been erected opposite the windows, the effect of which is to darken the room to such a degree as to make the proper examination of the specimens by the public impossible. This is all the more to be regretted as a descriptive handbook had been prepared in which an account of the collections was given case by case, while at the same time a compendious statement of Irish geology was afforded. There was every reason to hope that this handbook, taken with the collection it described, might be of great service in promoting the science of geology, and in providing accurate information regarding the geological structure and resources of Ireland. The director of the museum has provided another gallery for the collection. But the new accommodation is not quite satisfactory, and the amount of space is inadequate. A complete change of cases is necessitated. The collections must be entirely rearranged, and the handbook, on which so much labour had been bestowed, becomes practically useless. It is not stated whether the range of high buildings is an official work, but from the neglect to assert the right to ancient lights it may be assumed an ordinary owner was not the culprit.

## TESTING OF BUILDING MATERIALS.\*

WHEN in 1755 JOHN SMEATON proposed to employ cast-iron in "totally new subjects," he found everybody who claimed to possess experience in construction was opposed to him. According to him, "the cry then was, that if the strongest timbers are not able for any great length of time to resist the action of the powers, what must happen from the brittleness of cast-iron?" The knowledge of materials at that time was of the empirical sort. The cast-iron of 1755 was superior in quality to the cast-iron of 1855, but there was no test by which its excellence could be ascertained. Experiments were made in order to impart more precision to what was known of the material, but from the size of the specimens employed and the imperfection of the apparatus the trials appeared to be a sort of game, which, however interesting, could not be considered as having any importance to engineers. It was by guessing that JAMES WATT arrived at a section of a cast-iron beam, and from the thickness of the vertical part it is evident he was afraid to go too far from the example of a timber beam. TREDGOLD attempted more systematic experiments than seemed possible with a man who was so poor. He was followed by FAIRBAIRN and HODGKINSON, who were able to operate on large pieces. But the most that was then desired to be ascertained was simply the breaking weight. The various stages through which a specimen had to pass before it succumbed was not much noticed. FAIRBAIRN does not appear to have employed a microscope in his numerous investigations, and he was describing his own defects as well as those of the iron trade generally when he said:—"Ironfounders, managers and furnace-men appear to work under the impression of the non-importance of attention to the mixture of metals, and hence arise all the anomalous conditions of soft and hard, strong and weak irons, and many other disqualifications which might easily be avoided by closer attention to the quality and due proportion of each particular iron and the quantity of carbon and flux used in its liquefaction." After giving a recipe of his own for an efficient mixture in order to produce a strong cast-iron, FAIRBAIRN falls back on the old practice of trusting to individuals, for he says, "In ordinary cases the mixture may be left to the discretion of those accustomed to the management of the cupola and the furnace." In those most important investigations on the strength of materials which were undertaken by EDWIN CLARK in connection with the proposed Britannia and Conway tubular railway bridges the problem was also what weight was required to break a beam or a trial-piece? The changes which were accomplished in the atomic constituents of the various materials were disregarded. On that account the record of the costly experiments is rarely referred to by modern authors on the strength of materials.

It was creditable to the sagacity of FAIRBAIRN that he was not blinded by national prejudice to the value of experiments so different from his own which were instituted by the United States Government, in order to arrive if possible at some exact formulæ for the preparation of material for ordnance. He describes them as opening out a new field of observation. In those experiments chemical composition was sought. FAIRBAIRN was able to perceive that they were leading to more certain results than were likely to arise from leaving the process to the discretion of men who were accustomed to cupolas and furnaces. Writing of one series of experiments, he remarks:—"It will be observed that while there is a very great disproportion in the quantities of each single ingredient in the hot and cold-blast metal, yet there is nearly the same amount of several combined, such as the slag and allotropic carbon, the amount of silicium and combined carbon, or silicium and total carbon. These numbers are significant, for although there is not a great disparity between the amounts of total carbon produced by hot and cold-blast, yet the hot-blast has evidently driven off a portion of carbon from combination, so that the cold-blast contains two and three-fourth times as much combined carbon. The hot-blast metal, however, meets with some compensation for this loss

of carbon by reducing by its intense heat a larger amount of silica, and assuming silicium. The wide difference in the amounts of slag in the two metals is also remarkable. The slag and allotropic (graphitic) carbon, being of a brittle nature and not united with the iron, coat the crystalline plates of metal and diminish their surface of contact; and consequently it follows that the tensile strength of the metal must decrease partly in proportion to the increase of slag and allotropic carbon." In these words we have an indication of a process that revolutionised the production of steel, and which depended on its relationship with cast-iron.

The experiments of the United States Ordnance Department gave an impetus to one branch of science, and in consequence in no country is the strength of materials studied with more avidity. The new volume by Professor J. B. JOHNSON, of Washington University, on the "Materials of Construction," is evidence of the fulness of knowledge on the subject which has been attained. In it we have chemical analyses, reproductions of microscopic views, sections of materials under various conditions, and, above all, several hundreds of stress diagrams and other graphic representations of facts and laws. There are also woodcuts of all varieties of machines which are employed in testing materials and photographs of the results of testing. Of late years America has gone far beyond England in the production of works upon the science of building, and it must be allowed that we possess no volume which will bear comparison with Professor JOHNSON'S.

Opinions will, of course, be divided concerning the advantages of such minute knowledge. In the beginning of the century PEACOCK, the City architect, gained a reputation by his advice to adopt as a fundamental axiom in construction, "a little stronger than strong enough." In those days there was a liberal use of materials, and what PEACOCK said was no doubt inspired by his artistic desires. He wished to see buildings express strength, but since we have become acquainted with the exact breaking weights of materials there is a tendency to reduce dimensions to the minimum which municipal regulations will pass. Whether, with increased knowledge, there will be a still further diminution is a serious question. But without considering applications in practice, there is a satisfaction in becoming acquainted with all the peculiarities of substances which are the servitors of architects and contractors. It cannot be complained that Professor JOHNSON is reticent. He has utilised the tests that have been made in the arsenal at Watertown since 1882, the report of the French Commission of 115 members on the standardisation of the tests of materials of construction, as well as the labours of Professors BAUSCHINGER, TETMAJER and MARTENS. But there are many other aids available in America. The author says he has one list of original contributions to the subject which fills 140 quarto pages. Professor JOHNSON'S own labours are also of importance. About 40,000 of the mechanical tests on timber and timber trees for the Agricultural Department of the United States were made in his laboratory at St. Louis.

Professor JOHNSON begins with an investigation of the principles of mechanics underlying the laws of the strength of materials. Then he treats of the manufacture and general properties of the materials of construction. Testing machines and methods are next described. The fourth part treats of the mechanical properties of the materials of construction as revealed by actual tests. Among the appendices are examples of American specifications for iron and steel, besides an important report by M. BACLÉ on the resolutions of various conventions which were held for investigating the strength of materials, with the conclusions from them adopted by the French Commission. There is also a memoir of the late Professor BAUSCHINGER, of Munich, whose name is honoured wherever scientific teaching is pursued. He established the first testing laboratory in Germany, which has been adopted as a model in other countries. He devised new apparatus, and introduced improvements in those in use. GAUSS'S method of mirror readings was applied by him to measurement. He has treated of the strength of cements, mortars, building stones, the effect of fire on columns of iron and stone, the mechanical properties of wood, and, in fact, the records of his laboratory are an encyclopædia on the subject. Professor JOHNSON believes so much is due to the late Professor in

\* *The Materials of Construction: A Treatise for Engineers on the Strength of Engineering Materials.* By J. B. JOHNSON, C.E., professor of civil engineering in Washington University, St. Louis, Mo., &c. New York: John Wiley & Sons. London: Chapman & Hall, Limited.

developing the scientific testing of materials, he has introduced BAUSCHINGER'S portrait as the frontispiece to the volume, and the German's influence is exercised throughout the pages. It is to be regretted that so little is derivable from English investigations.

Although Professor JOHNSON is an expert in testing, and it may be on that account, he has no exaggerated notions of what can be discovered by experiments on specimens. For example, he says that "chemical tests of stone are of little value in themselves, but taken in connection with microscopical examinations they may be of considerable value. In fact, as a general rule, no chemical test need be made unless it is required to explain the microscopic structure already examined." The freezing test he considers to be at best only a comparative test. On the subject of the weathering of building stone he remarks:—"A single illustration of actual weathering for many years is worth more than all the artificial tests which can be applied." The Professor has, however, much faith in the aid that can be given by the microscope when properly used:—

The microscopic test consists in the preparation of very thin slices or sections of the stone, and examining these under a microscope. A thin chip of the stone is first ground with emery to a plane on one side and polished. This side is then glued to a piece of glass with Canada balsam, and the other side ground and polished in a similar manner. The section is made so thin that it is quite translucent, and sufficiently transparent to read a printed text through it. It is then mounted regularly upon a microscope slide and covered in the usual manner. The examination under the microscope (magnifying about 25 diameters) consists in—

1. The observation of the structural arrangement.
2. The identification of its constituent parts (by an experienced lithologist).
3. A study of the character of the cementing bond.

The microscopic test, when made by an expert lithologist, will reveal more accurately the character and physical composition of a rock than any other single test. After such an examination, the question of further study upon the specimen can be decided more intelligently.

Many of the materials required in construction have been employed for centuries without any thought of tests on the part of those who specified them. But one of the effects of the access to power in industrialism of electricity has been a demand for new tests of iron and steel. Mr. LAYMAN'S chapter on the magnetic testing of those materials suggests that we may expect new revelations concerning the causes which affect many materials. His last words are enough to show that at least in one department continuous tests are indispensable:—

It is also desired to place great emphasis on the need as well as desirability of thorough, accurate and continued magnetic testing of materials. On the scientist's part this necessity is fully appreciated, for he understands that just as the present knowledge of their magnetic properties and the successful use of iron and steel in electrical manufactures is the result of careful testing, so also is future development along these lines dependent on testing. On the manufacturers' part there is a constantly growing appreciation of the great advantages to be gained from testing. The electrical manufacturer, knowing how great may be the variation in magnetic quality of the materials furnished him, is keenly alive to the fact that he cannot maintain nor advance the standard of his apparatus without testing. The iron and steel manufacturer, in turn, is coming to see that he cannot much longer furnish for electrical work such materials as are included in his regular line of manufacture. Electrical work is beginning to demand rather than accept, and soon must have materials which are shown by scientific study to best meet the requirements of this department of industry. The situation is one in which the consumer must not only protect himself, but lend all the assistance within his power to the scientific study of magnetic phenomena, while the iron manufacturer must, by the limitation of trade competition, know from his own investigations the quality of the materials he is turning out, and the part played by physical and chemical conditions of manufacture. From every point of view is clearly evident the importance of the magnetic testing of iron and steel.

We need not be alarmed about the use of the two materials in building and engineering construction, for if any new source of danger can be discovered it will be announced by Americans, if not by Frenchmen or Germans.

## BETTERMENT.

LOCAL authorities have to please the multitude of their constituents in order to retain their positions. With the crowd there is a desire of justice to the extent of wishing to have the masses brought up to the level of the classes, and their representatives have to appear in favour of the upheaval. Now it cannot be denied that in appearance at least many causes help to make the task more difficult in modern times. The progress which is supposed to be characteristic of England during the last fifty or sixty years has benefited in an especial degree many of those who were proud to be obstacles to all improvement. The history of private bill legislation exemplifies the fact most impressively. It will be found that the opponents of new streets and the like, who increase the cost of an Act enormously to a municipality, are generally the men who derive the largest financial advantage from the works. In the hope of diminishing the virulence of their opposition unusually liberal arrangements have to be made with them for any property which may be required, but the indirect gains are much more munificent. Ratepayers cannot help grumbling at the mischance which rewards those who are so little deserving. Another object lesson which is also irritating is the marvellous enhancement of property which arises entirely from the good sense exercised by tenants. In new districts in London and in many provincial towns the occupants of shops often have to wait patiently for years before success has been attained. Time at first goes slowly, but afterwards it passes faster than at a Derby race. The lease expires and a tenant is found who is willing to pay according to the new conditions of the district. The outgoing tenant is sure to have sympathisers and they endeavour to strengthen the prejudice which arises against all who, without any merit of their own, become the favourites of fortune. There is, of course, another aspect of the case. Public improvements inevitably bring losses to people, to landlords as well as tenants. But the crowd will not discriminate, and it is concluded that somehow owners are always lucky in escaping, and if there is a decline in the value of their property in one spot it is amply compensated elsewhere.

It happens also that property owners, or rather owners of sites of buildings in towns, are often brought into collision with municipal authorities. The latter are not more than human, and when they find themselves treated as inferior beings can we be surprised if they retaliate? The consequence is that the number of public bodies who are willing to apply to Parliament for power to recognise the principle of "betterment" is increasing. This year the Glasgow Corporation, that cannot be considered as wanting in discretion, can be counted among the adherents, and Mr. John Honeyman, R.S.A., is compelled to take the trouble of opposing the proposals. He will find many architects and surveyors who will take sides with him, but the public cannot be expected to judge of profits with the clearness which technical experience imparts. As long as the value of property increases through improvements which were carried out at the cost of ratepayers, and for which benefit not even gratitude is expressed by the owners, we must expect grumbling. At one time in such cases it seemed only an affair of individuals, but now, when property can be possessed by municipalities, it is natural to believe that all extraordinary rises in the value of property should in some way be followed by a proportionate reduction of taxation.

It seems to us that in his very carefully written pamphlet Mr. Honeyman has overlooked this third party or factor. He says it requires two to make a bargain, but in cases of betterment there is a third party more omnipotent than either. If improvements are for the public advantage and cause a depreciation in value some acknowledgment to the owner should be authorised, and "worsement" should therefore be recognised. It may be granted that neither the degree of betterment nor worsement can be calculated immediately, but after a longer or shorter term it can be ascertained with as much accuracy as is possible when dealing with variable qualities. A case which occurred in Glasgow, cited by Mr. Honeyman, suggests the danger of valuations on an assumed basis before time has exerted its influence:—

"About twenty years ago a builder purchased a plot of ground from the Improvement Trustees at the rate of 8*l.* per square yard, and the price was converted into a feu-duty at the rate then current. On this ground he erected a substantial and costly block of buildings; but about twelve years afterwards the Trust sold 'land in the neighbourhood,' within the same sphere of betterment, at the rate of 4*l.* per yard, thus immediately reducing the value of the first builder's property by four to five thousand pounds. The first builder, thinking that his position would be improved by buying up his feu-duty and that he had some claim on the favourable consideration of the Trust, entered into negotiations with them with this result—that they absolutely refused to take the capital sum represented by 8*l.* per yard, and insisted on the duty being capitalised at the present exceptionally high rate, thus practically adding about 16*s.* to the cost of land which by their own

act had been so greatly depreciated. This case should be sufficient to demonstrate how unjust it is to exact a charge for the alleged permanence of betterment without recourse in the event of this proving fictitious."

The case in question is undoubtedly not equitable. It would not, however, excite much attention if it were recorded of an ordinary landowner. Corporations are fallible, and in future transactions we suppose the Improvement Trust would show more consideration to investors.

Mr. Honeyman considers that the proposals of the Glasgow Improvement Bill concerning betterment "really amount to the introduction of the thin edge of the wedge of legislation authorising the taxing the land values, whether anything is derived from the land or not." We have more faith in the good sense of a northern corporation. What we imagine is sought is to prevent the repetition of such remarkable cases as are familiar in London, where an improvement becomes for some people a sort of magic wand that turns everything into gold. It is possible that in every change there will be inequalities, but it is hardly fair to compare a rise in the value of property an hundredfold with cheap fares of tramcars or the introduction of electric light into a particular street. Nor can we agree with Mr. Honeyman when he wishes to see the working-classes brought back to the districts in which clearances had become compulsory. Improvements in communication allow of the working-classes living in districts which are a little remote from commercial centres in a city without much inconvenience to themselves and with many advantages. Mr. Honeyman says:—

"We wish to see the poor people housed healthfully and cheaply on the ground they now occupy, and there are few insanitary districts in Glasgow where this could not in great measure, if not altogether, be accomplished were it not for injudicious municipal interference. There are more ways than one by which a poor population may be driven from a district, but probably the most effectual method is to pull their houses down, and then make the ground so dear that it is impossible to build houses upon it which they can afford to pay for. Now, charging for betterment must necessarily tend towards that result. This charge, as we have seen, like any other, must be borne by the occupiers of the new buildings. The inexpediency of doing anything of this kind which can possibly be avoided must be at once apparent to all who have taken any interest in the housing of the working classes.

"The public and public men have never properly realised the important bearing of cheap rents on the health of the community. Attention has been too exclusively directed to the overcrowding of dwellings on restricted areas, and the worse evil, so forcibly and scientifically expounded by Dr. Chalmers in his recent pamphlet—the overcrowding of the dwellings themselves: its cause and only cure—has been far too much overlooked. Municipal authorities do not seem to see that if they order a man to occupy a house which cannot be produced for less than 12*l.* per annum when he can only afford 6*l.*, they might just as well insist on the man taking beefsteak and champagne to his dinner every day when he can only afford oatmeal porridge. The overcrowding of dwellings is a necessary consequence of high rents. If a man cannot afford the rent, he has no alternative but either to become a lodger or to take lodgers. Let any one try to put himself into the position of the poor man with a wife and family reduced to such an alternative, and he will probably realise as he has never done before the misery and discomfort which either alternative may produce. If municipal philanthropy be permissible at all it cannot take a less objectionable form than the provision of cheap building ground for the erection of houses for the poorer section of the working classes—not in the outskirts or the suburbs, but in the congested localities where these classes prefer to live. Nothing would more directly tend to promote social wholesomeness, or more readily command the sympathy and approval of the whole community."

Mr. Honeyman has given much attention to the problem, but the majority of those who know what public improvements cost will hardly agree with him in believing that ground which is acquired at so much outlay should be dedicated to occupiers of the humbler classes. That would be an unwise set-off for enriching a few landlords at the cost of the public.

### DYNAMOS.

A PAPER, which was read by Mr. W. M. Mordey before the Institution of Electrical Engineers at the last meeting of the session, was by far the most important one. It deals with a subject which must become as familiar to the architect and borough surveyor as the steam-engine or pump. Mr. Mordey opens his paper by saying, "The development of the dynamo has been very rapid. The subject from the first proved attractive to engineers and scientific men, as well as to commercial people." He then goes on to describe the methods by

which the dynamo was developed. Up till 1886 the dynamo was constructed according to the ideas of the designers, and by the result of experience. Rapid progress was facilitated greatly by the paper read by Drs. J. and E. Hopkinson in 1886 before the Royal Society. The next paper which was of an epoch-making character was that read by Mr. W. B. Sayers in 1893 before the Institution of Electrical Engineers. For some years past little or no advance has taken place, and the dynamo has come to be looked upon as having reached its full development.

Mr. Mordey goes on to discuss whether it deserves its high reputation, and concludes that it does as a working machine, as it is reliable, durable, highly efficient, and has good regulating qualities, good collection, even in some cases with fixed brushes and varying load. He then points out that these good qualities, possessed by the best machines, are obtained at a great expense by the lavish use of costly material. The field magnets are too large, both as regards length and section. If dynamos which require a lavish expenditure of material to attain a desired end are unsatisfactory, then the best modern dynamos leave plenty of room for improvement. Mr. Mordey gives one simple fact to prove this:—"One-tenth of the present exciting power would amply suffice to magnetise the iron of the magnetic system (and a gap sufficient for clearance) to its required value, the other nine-tenths may be looked upon as spent, directly or indirectly, in overcoming armature reaction." This means that one-tenth of the power is used to produce the required magnetism, and the other nine-tenths in preventing sparking at the higher loads.

The lines along which the improvement will develop is in obtaining more work from a given value of material and labour, while retaining the good working qualities.

Mr. Mordey further says that the output is limited by sparking, heating, questions of regulation (*i.e.* drop in pressure at a fixed speed as the load is increased), and by the strength of working parts. It is better that the output should be limited by heating rather than sparking, that overloading may be possible for short periods. The life of a dynamo depends greatly on its cool working. Too much attention is being paid to reducing the heat losses, while too little is given to getting rid of heat when generated.

Good dynamos do not spark appreciably, but they are very expensive in cost or in magnetising current. Mr. Mordey thinks that a great deal of this cost can be prevented, especially the loss in magnetising.

If a dynamo could be made to run sparkless, having only sufficient air space between the iron of the armature and iron of the field magnet for clearance (this can be in a 5 horse-power machine  $\frac{1}{2}$  of a millimetre, in a 100 horse-power  $1\frac{1}{2}$  millimetre, in a 300 horse-power 2 millimetres) and with a short magnetic circuit, it would require very little excitation. The effect of putting a load on the armature would be to enable the magnetism of the armature to oppose and contort the magnetism of the fields, and sparking and loss of voltage would be the result. To render this reaction less the magnetic circuit of the armature must be made worse, and consequently the air gap is increased. To do this we must add field winding, add length to enable the wire to be wound in it, add section to the field magnet to convey the leakage magnetism caused by the increased air gap, and so on cumulatively until we have the excitation thirty to fifty times as large as originally, and have made the magnet larger (in length, section and in copper). The whole of this increase to reduce armature reaction.

Taking the Edison-Hopkinson dynamo of 1886, the distribution of the exciting current is for it:—

Air gap, 80.2 per cent.; compounding (increasing magnetism as load increases), 9.6 per cent.; armature core, .68 per cent.; field cores and yokes, 9.53 per cent.

The important part, the armature, only takes .68 per cent.; the other 99.3 per cent. is used in getting the magnetism through the rest of the circuit.

In earlier days (before 1886) Mr. Mordey says that the subject of debate used to be, What part of a dynamo should be the heavier? Now it is the object to make each part as light and inexpensive as possible.

A field magnet should be a mass of iron so arranged as to complete the circuit between one side of the armature and the other in as little distance as possible, and with as small a cross-section as is consistent with economy.

Mr. Mordey sums up the two kinds of armatures used—smooth-cored and toothed—in a very admirable manner. The former is preferred in this country, the latter on the Continent and in America. The smooth-cored armature gives very good results. It collects sparklessly and regulates well, but it is expensive of material, and is mechanically unsatisfactory when compared with a toothed armature.

The toothed type collects badly and is not a good regulator, but it has many good qualities, so it is important to improve it. Its latent advantages over the other are:—1. Small magnetising force required. 2. Small magnetic leakage. 3. Absence of eddy currents in armature conductors. 4. Armature conductors can

be solid. 5. Drag on armature conductors small. 6. Conductors are easily supported. 7. Its cooling qualities are good. 8. It is cheaper to make.

The advantages are not all realised at present. At least, Nos. 1, 2, 3 are not realised to the extent they should be.

Mr. Mordey calls attention to the very erroneous method of considering the magnetisation of a circuit. The mistake is to begin by magnetising the field magnet when the real object is to get the armature magnetised. This was recognised by Professor Forbes, and realised by Erckemeyer when he placed the exciting coil directly round the armature. By this means more magnetism goes through the armature than through the field magnet, and leakage is absolutely beneficial.

The Sayers winding is a still further development of this idea, and was led up to by the investigations of Hopkinson, Swinburne and others. Sayers obtained a solution of the problem when he arranged his armature reaction to help the field instead of opposing it, by giving his brushes a lag, *i.e.* placing them not forward from the middle position between the poles, but behind as the load increases. This in an ordinary armature would give rise to serious sparking, consequently he placed in each connection from the armature to the commutator an auxiliary coil which opposes and prevents the mischievous sparking.

Then follow the paragraphs which are the *raison d'être* of the paper, which describe the very latest advance in the winding of armatures to minimise armature reactions and the attendant evils, without any extra cost over an ordinary armature, and with the result that the full load-exciting current is much reduced and the regulation improved. The description of this is rather technical, and it is difficult to simplify it without sacrificing accuracy.

As is well understood, the ordinary ring-winding consists of a number of coils on the ring equal to the number of segments on the commutator, the end of each coil being joined to the beginning of the next, the connection to the commutator being taken from this joint. The winding described by Mr. Mordey is similar, but a portion of each coil is wound on the ring in advance of the rest by a distance equal to the air gap between the pole pieces. The result of this is that when one part of the coil is under the horn of one pole piece the rest is under the horn of the other. The E.M.F. of each portion of the coil is opposing the other, and the result is that when this coil is short-circuited under the brush, instead of there being a large current through the coil which must be broken when the coil is open-circuited, there is none, the pressures neutralising each other, and there is no armature reaction due to the short-circuited coil. If the two parts of each coil are not equal, the field may be strengthened in a dynamo as the load increases, instead of being opposed, and thus a similar effect is obtained to that with a Sayers winding, but with the difference that all turns on the armature are active. Several excellent diagrams are given which further elucidate the arrangement, and also the results of tests of the winding. It is claimed that at least half of the field winding is saved, and that a lower initial excitation is sufficient, while the machine will run practically sparkless.

With reference to this improvement, further experiments will, of course, be necessary, but at any rate a great advance will be made in the cheapening of dynamos, while retaining the sparklessness now only obtainable at a great expense, and in the best machines.

The paper goes on to discuss the subject of brushes and collection, and this part is a complete study of the subject in a very small space. It may be said here that the author has all through the paper treated the subject in a clear, concise and direct manner, and has kept wonderfully within the scope of the paper. It is, of course, a wide subject, but he has not given way to the temptation to discuss fully the side issues, while leaving the main subject incomplete, which so often vanquishes the writers of papers.

A few of the results of the inquiry into brushes may be of practical use to those who have dynamos under their notice which give trouble from sparking. The current should be induced to enter the heel of the brush and checked at the toe, but the brush as a whole should be of low resistance. The best brush is one which is made up of laminations of copper foil or carbon plates, each lamination insulated from the others along its whole length at the toe and only a portion of its length at the heel, by means of, say, an insulating cement; the top ends of these sheets soldered together, the contact-plate being fixed to the back sheet.

Such brushes have been found, says Mr. Mordey, to give a better collection, and with only half the lead required by copper-gauze brushes. Carbon brushes act in a similar way to copper-brushes constructed in the above manner, but the area of the carbon brush should be at least 1 inch for every 75 amperes carried.

The next division of the paper deals with the question as to whether there is any drag on conductors buried in the armature core, and the author gives particulars of experiments made by

him which prove that even when the conductor is not completely buried there is very little drag on it.

A short portion of the paper deals with excitation of the field magnet by the armature; it is only of theoretical interest at present, so there is no need to go further into the subject here.

The use of internal field magnets, *i.e.* dynamos where the field magnet is inside the armature, is advocated, as being an economical arrangement, owing to less magnetic leakage and a shorter magnetic circuit. The Ayrton and Perry motor, introduced many years ago, is mentioned, in which the field magnet and brushes revolved and in which the armature and commutator were stationary. The objection at present in force, says Mr. Mordey, is that the relative position of brushes and field cannot easily be altered while working, but the removal of this necessity by the various devices already mentioned leaves the way open for such machines. Even now on tramway and other motors the brushes cannot be altered while running.

The general result of the paper is to show that the dynamo is not yet a perfect machine, good qualities being too expensive; toothed armatures are better mechanically and electrically than smooth-core ones if the armature reaction and sparking can be remedied cheaply. It also explains a new method of winding by which this can be accomplished in an inexpensive manner.

The paper also goes fully into the considerations affecting the sparking, armature reactions, heating and expense of armatures, the theory of brushes, excitation of the fields by the armature, or, more correctly, the self-excitation of the armature and the possibilities of the internal field-magnet form of machine.

The paper stands out pre-eminently as the only really important paper on the subject of dynamos since that of Sayers in 1893, and it will rank in importance with the paper of Hopkinson.

It is to be regretted that such an excellent paper should have been crushed into the last meeting of the session, as more time could have been devoted to it with great advantage.

We notice that Mr. Mordey prefers to spell the plural of dynamo—"dynamoes."

#### DISCOVERY OF GREEK PAPYRI.

ONE of the largest and most important finds of papyri in Egypt has been made during the last winter by Mr. Bernard P. Grenfell and Mr. A. S. Hunt, of Queen's College, Oxford, working on behalf of the Egypt Exploration Fund at Behnesa, the ancient Oxyrrhynchus. The site of the old town, says the *Times*, which is  $1\frac{1}{4}$  mile long by half a mile broad, and is situated on the little explored edge of the western desert between Fayum and Minya, had remained almost untouched by dealers and antiquity seekers, and offered to the excavators—what is in Upper Egypt now almost a thing of the past—a practically virgin field. Very few remains of buildings were discovered, the place having been long used as a quarry both for stone and bricks, but many of the ancient rubbish mounds yielded a rich store of papyri, while in three mounds the quantity of rolls found together was large enough to warrant the assumption that part of the archives had been thrown there at different periods.

The papyri range from the Roman conquest to early Arab times, each century being largely represented, and are for the most part written in Greek, with a sprinkling of Latin, Coptic and Arabic. As the excavators had not time for deciphering, very little is yet known of their contents, but Mr. Grenfell's chief hope in digging the site of Oxyrrhynchus—the prospect of finding early Christian documents—would seem to have been to some extent realised. Among the papyri discovered at the very beginning of the excavation was a leaf from a third-century papyrus book, apparently containing a collection of Logia, or sayings of Christ. Some of those found in the fragment are not in the Gospels, while others exhibit several divergencies from the text of the parallel passages in the Gospels. The age, character and value of these Logia are likely to be the subject of considerable speculation, but there is no foundation for the entirely unauthorised and inaccurate reports connecting this discovery with the Logia which Papias states were collected by St. Matthew. It is hoped that when the papyri come to be examined in detail further discoveries of early Christian records will be made, as well as of fragments of lost classical literature, since in some of the mounds, notably the earlier ones, an unusually large proportion of the papyri found were written in uncials.

The cream of the collection in point of size and condition, consisting of 150 large and complete rolls in many cases several feet long, has been retained by the Gizeh Museum, the rest of the collection, of which the bulk is, of course, in a very fragmentary condition, is on its way to England, where the systematic examination and publication of it will be undertaken by Messrs. Grenfell and Hunt.

Besides papyri the excavators found a considerable number of coins, about 200 inscribed ostraca, bronze and ivory ornaments and other small objects of the Roman and Byzantine periods.

## LONDON BUILDING ACT, SECTIONS 13 AND 14.

UNDER section 14 of the London Building Act 1894, where a new building is erected at a less distance from the centre of the roadway than is permitted by the Act, the Council can serve a notice on the owner, occupier or builder requiring the building to be set back. Accordingly the London County Council applied for penalties against Rowton Houses, Limited, buildings which are in Churchyard Row, Newington, for not obeying a notice served upon them by the Council under the London Building Act 1894, section 14. Mr. A. A. Hopkins, the magistrate, having heard the evidence of Professor Banister Fletcher, district surveyor, and other witnesses, delivered the following judgment:—

These two summonses (Fletcher *v.* Farrant and Berry *v.* Rowton Houses) may be treated as, in effect, one summons by the London County Council against "Rowton Houses, Limited," for penalties for not obeying a notice served upon them by the Council under the London Building Act, 1894, section 14. The building in respect of which the complaint arises is Rowton Houses, Churchyard Row, Newington, and is now, as a building, practically complete. Churchyard Row is a carriageway bounded on one side by the wall of Rowton House and on the other by the open space of the churchyard of St. Mary. There is no dispute about the facts; I need not go into them minutely. It comes to this—that it is admitted that every fact necessary to raise this question must be found against the defendants.

Perhaps I ought to say one word as to how the case came here. The London County Council takes these proceedings, as I understand it, to establish its general authority in such a case as this, and to avoid the making of a precedent. But its counsel very fairly mentions that there was a time in the history of this building when the Council invited the defendants to apply for its consent to this building as it now stands. At that time the Council was, no doubt, prepared to consent to it in its present form, but the defendants declined to apply, and went on without the formal blessing of the Council, standing out, I suppose, for the exact rights of all builders. Without the consent of the Council they did that which they would have done with its consent, and, as far as this particular case is concerned, I do not understand that any person or building is any the worse off, or that anything has happened in the erection of this building which would not always have happened if the Council had been asked for and had given its consent.

The allegation which concerns me is that the defendants' building is so high as to infringe the last proviso but one of sub-section 5 of section 13 of the London Building Act of 1894, and if that proviso applies the building is certainly too high by many feet. The statutory height having been exceeded the London County Council served the defendants with the notice under section 14 requiring them not to complete and roof in at the statutory height, but to set back their external wall from the ground upwards to a certain prescribed distance from the centre of Churchyard Row. That procedure seems to be right under the statute, and I suppose it is only another curiosity of the Building Act 1894. The defendants, of course, did not comply with that notice, and the question is whether they must.

Rowton House (I have been to see it) is a large and handsome building, built round a large quadrangle, and is capable of providing accommodation for some 800 people. It is to be open, I believe, to men only; the accommodation includes board and lodging and the use of various conveniences and recreation-rooms; it is in fact, as Lord Rowton describes it, an immense poor man's hotel. It is, as a building, a great improvement upon the thirteen dingy cottages with their gardens that formerly occupied the site, but it is said to offend against the proviso which provides "that no dwelling-house to be inhabited, or adapted to be inhabited, by persons of the working class, shall, without the consent of the Council, be erected to a height exceeding the distance of the front wall from the opposite side of the street." Now if, say, the Gordon Hotels Company had done exactly what the defendants have done in this matter and after complying with the requirements of the statute, as the defendants complied with them, had erected on this very site one of their palaces of entertainment for their customers, Mr. Avory must, I think, admit that they might go to any height they pleased, and that no question could arise as to the height under this proviso, because the Gordon Hotels could not be said to be within it. Now for all the purposes of the London Building Act that I can think of, I can see no possible difference between, say, the Gordon Hotels Company building a rich man's hotel and Rowton Houses, Limited, building a poor man's hotel. On what ground is a restriction to be placed on the one that does not apply to the other? Of course the answer is that the statute has said so by providing "that no dwelling-house to be inhabited by persons of the working class shall be erected to a height exceeding," and so on; I do not so understand the words.

I do not want to go through the various clauses and interpretation clauses, or to criticise the wording very minutely. A very considerable experience of the diffuse and difficult lan-

guage of this highly technical statute has taught me that a minute examination of its language often lands one into a maze of contradiction. I prefer to take the larger and more general view, and to reason from the analogy of the position of two typical hotel builders. Doing so I have to ask myself whether these words are apt, and sufficient to impose upon the one builder an enormous restriction from which the other is wholly free. I think they are not. I understand them to be a prohibition intended to prevent in the future the building of narrow alleys and courts and little dwelling-houses, throughout the length of which the houses are higher than the courts are wide, and I have come to the conclusion that they have no application to such a case as this. Before I conclude I want to say that, while all the bare facts necessary to raise this question, must be found against the defendants, yet I am strongly of opinion that whether the case is viewed as an omission to obtain a consent they might have had, or as an instance of a great building improvement upon a site where air and light advantages are conspicuously prominent (for it must not be forgotten that the opposite side of Churchyard Row is an open-space churchyard) I am strongly of opinion, I say, that all the real merits are with the defendants. I dismiss the summonses.

Mr. Naldrett: Upon that I ask your Worship to give the costs to the respondents, and I think it is necessary to ask you to fix the amount.

The Magistrate: I have considered the question of costs, Mr. Berry, and I must hear Mr. Avory or you upon it. I suppose you cannot successfully contend that, bringing a test case of this sort here, you ought not to pay them.

Mr. Berry: I think we ought to pay the costs, sir, and perhaps, if the Council wish to go on, you would be kind enough to state a case, which possibly is an additional reason why we ought to do what is right with regard to paying them.

The Magistrate: I could not refuse to state a case, because there is plenty of argument to be got out of this Act of Parliament.

Mr. Berry: We came here because we were rather invited to raise the point, otherwise we might have settled the case in a particular way; that is all I wish to say about it.

The Magistrate: I allow 15*l.* 15*s.* costs.

## COMPETITIONS IN AMERICA.

AN agreement on the subject of engaging in competitions has been signed by the following architects of New York:—Messrs. George B. Post, McKim, Mead & White, Bruce Price, Henry Rutgers Marshall, R. H. Robertson, H. J. Hardenbergh, R. W. Gibson, Babb, Cook & Willard, Edward H. Kendall, George Keister, Rossiter & Wright, Carrere & Hastings, Berg & Clark, Renwick, Aspinall & Owen, James Brown Lord, Charles C. Haight, Clinton & Russell, R. H. Hunt. We give the full text of the document:—

The undersigned architects, being constantly invited by those not conversant with architectural practice to participate in competitions upon conditions with which it is impossible to comply, announce that they have mutually agreed that they will enter into competition upon the following terms only:—

That in any case the undersigned shall be paid at least a sufficient sum to reimburse them for their cash outlay in preparing their competition drawings.

That in case of limited competition the number of competitors shall be definitely named, and that the number shall not be increased without the consent of all competitors.

That it shall be definitely understood that the ordinary fees as published by the American Institute of Architects shall be paid as compensation for his professional services to the successful competitor.

That in work of any serious importance a professional advisor or advisors shall be appointed to act with the party instituting the competition in the preparation of a proper programme, which shall be definite in its specifications of requirements and explicit in its statement of the drawings required and their character and of the various rules which shall govern the competition.

In the opinion of the undersigned it is very desirable that the professional advisor or advisors should be practising architects, and the undersigned suggest that the best result can be gained by first appointing the architects to compete and by inviting them to meet with the party instituting the competition for the purpose of consultation with regard to the preparation of the programme of competition and to nominate the professional advisor or advisors.

It shall be the duty of the professional advisor or advisors to examine all drawings submitted by the competitors, and to place out of competition any competitor who has not submitted his designs at the date fixed for their reception, or who presents details or models which are not called for, or whose drawings do not conform exactly in number and character with the requirements of the programme, and that if placed out of competition his plans shall receive no further consideration by the party instituting the competition.

Inasmuch as the object of a competition is to adopt the general *motif* of a design to be further elaborated, and to select an architect for the work rather than secure plans perfectly studied in all of their details, the undersigned will enter upon no competition unless it shall be agreed that an award shall be made and that an architect shall be appointed on the consideration of the relative merits of the several schemes as shown by the drawings submitted, and that no demand shall be made for additional drawings or for a new competition.

The undersigned are of the opinion that all designs should be signed by their authors, and also that it is desirable that each competitor who has qualified by having his designs accepted by the professional advisor or advisors as complying with the terms of the competition, shall have an opportunity to personally explain his design to the party instituting the competition in the presence of the professional advisor or advisors.

### THE CANTERBURY CHAPTER-HOUSE.

ON Saturday the chapter-house, Canterbury, was opened after restoration, by the Prince of Wales. Although not comparable with the examples at Salisbury, York and Wells, the Canterbury hall measures 93 feet by 35 feet. Around the lower part, rising from the stone seats, is an arcade of columns and arches. The roof is of timber elaborately panelled.

The following address was delivered by Dean Farrar:—May it please your Royal Highnesses, my Lord Archbishop, my Lord Duke, my lords, ladies and gentlemen,—I will only occupy your attention for one or two moments while I say a very few words about this chapter-house, for the opening of which, after its restoration, your Royal Highness has done us the distinguished honour of visiting Canterbury to-day. We are this year celebrating the thirteenth centenary of the history of our cathedral, and three days hence will occur the 1,300th anniversary of the baptism of King Ethelbert, in consequence of whose conversion Canterbury became the first Christian English city and Kent the first Christian English kingdom. Parts of our cathedral are even more than thirteen centuries old, for it occupies the site of an ancient Roman and British church. In 1012 the church and city were burnt down by the Danes, when St. Alphege, who is represented on that window with the ox bones in his hands with which they pelted him to death, was martyred. In 1067 the cathedral was again burnt down, and Lanfranc, when he became Archbishop in 1070, rebuilt the Norman cathedral, of which great parts still remain. It was into Lanfranc's Norman chapter-house that Archbishop Becket came with his monks and chaplains on that memorable winter evening of December 29, 1170, just before his murder in the adjoining Martyrdom. The chapter-house was rebuilt in 1304 by the princely Lord Prior Henry, of Eastry, to whom is due all the work below the line of the arcading. It was completed about 1400 by another of my great building predecessors, Prior Chillenden. Roughly speaking, therefore, we are in a building of which the walls are partly 800 years old, the lower division 600 years old and the upper division 500 years old. The windows on the north side were always panelled as they are now, for they formed the southern wall of the great dormitory of the monks. Those on the south side which had been plastered up have now been reopened and reglazed. To Prior Chillenden are also due the great eastern and western windows with their quadruple tiers of stained-glass, of which the eastern, having been destroyed in the Puritan epoch, has been now refilled with stained-glass by Mr. Hemming. It represents the figures and symbols of all who have been most famous in our cathedral history, from Queen Bertha, the first Christian English queen, to Her Gracious Majesty Queen Victoria, who this year completes the longest reign of all our sovereigns, and is the most beloved; and from Archbishop St. Augustine to Archbishop Benson, whose successor, the ninety-third Archbishop of Canterbury, has offered up the prayers to-day. The window contains the figures of all the saints and kings who have most enriched our resources and adorned our annals; and among these your Royal Highness's great ancestor, the famous Black Prince, who built the lovely chantry in the crypt and is buried in our Trinity Chapel. His ostrich feathers are represented on that window, as they are on his tomb, and I am only saying that which the whole English nation will attest if I say that his world-famous motto "Ich Dien" has received most noble meaning and illustration in the ungrudging and unwearied services of your Royal Highnesses to every work of national progress and national philanthropy. This east window is the splendid gift of the Freemasons of Kent, and will be commemorated by a masonic gathering here in the autumn. Their Provincial Grand Master, Earl Amherst, represents them here to-day, and if I may venture, Sir, to give a desperate, audacious hint in the presence of your Royal Highness, as Grand Master of the Freemasons of England, I may say that if each English Freemason would, in commemoration of the honour you have done

us, give one shilling, the west window also could be filled with glass—there might be another royal and masonic celebration of the sixtieth year of Her Majesty's reign and of our great 1,300th anniversary. In 1644 this building, though it is not consecrated and has always been used for secular purposes, was arranged as a sermon house, and in the north-east corner was a royal gallery to be used whenever the king and queen were present, which in those days was a common event. The building gradually fell into a melancholy aspect of decay and disrepair, from which, by the aid of our restoration fund, it has been restored under the direction of Mr. Hemming and of our distinguished architect, Sir A. Blomfield. We trust that for centuries to come it may add to the usefulness and dignity of the cathedral; and, in conclusion, we most heartily thank your Royal Highnesses for a visit which will ever be memorable in the annals of our cathedral and of our city, and will help to impress on the imagination of the English people the fact that we have now enjoyed 1,300 years of the blessings of the gospel of Christ, and that those long centuries which we celebrate to-day should mean a mighty national advance in magnanimity and nobleness, in all that is lofty and generous and good. Once more we offer to your Royal Highnesses our loyal and grateful homage, and I will now ask your Royal Highness to declare this chapter-house opened for the many useful purposes of education, of philanthropy, and of the prosperity of the diocese, the Church, and the people for which it will henceforth be set apart.

### THE SURVEYORS' INSTITUTION.

THE annual general meeting of the members of the Surveyors' Institution was held on Monday, May 31, at the temporary offices, Savoy Street, Strand, Mr. Daniel Watney, the president, in the chair. The twenty-ninth annual report of the Council, submitted by the secretary, showed that during the last twelve months there had been a net increase of 112 in the number of all classes on the roll, the total membership now being 2,702. The entrance fees showed an increase of 169%, but there was a net decrease in subscriptions from all sources of 22% during the twelve months to Christmas last. The total revenue for the year was 7,334%, and the expenses amounted to 5,596%. The total investments calculated at current prices now represented a sum of 35,226%. At the preliminary examinations in January last, held simultaneously in London, Dublin and Manchester, there were 133 student-candidates, of whom 91 passed; and of 236 candidates who offered themselves for the professional examinations 151 passed. The Council congratulated the members on the progress of the Institution during the past year in every one of its numerous channels of activity. The report was adopted on the motion of Mr. A. Harston, seconded by Mr. Ernest Swain. Votes of thanks having been passed to the auditors and to the President and Council, the President presented a number of prizes gained by students in the recent examinations. On the motion of Mr. Robert Vigers, a vote of thanks was passed to Mr. Watney for his services as President during the past two years, and subsequently Mr. Watney invested the incoming president, Mr. Christopher Oakley, with the President's chain of office.

### IRON AND STEEL INSTITUTE.

THE autumn meeting of the Iron and Steel Institute of Great Britain will be held at Cardiff from August 3 to 6 inclusive in the house of the South Wales Institute of Engineers. The proceedings will comprise the reading and discussion of papers and visits to works of interest, besides several social gatherings, the second and third items being distinctly prominent in the programme. On August 3 there will be visits to the Bute Docks, the Cardiff-Dowlais Works and other establishments in the vicinity. On August 4 the Penarth Docks and works on the Taff Vale Railway will be inspected. On the following day a visit will be paid to the Dowlais and Cyfarthfa Steel Works, and on August 6 there will be a whole-day excursion to points of interest in the neighbourhood. On the evening of August 3 the Mayor of Cardiff will hold a reception at the Free Art Library, Art Gallery and Museum building. On August 4 the members and the ladies accompanying them will be invited to a ball by the Marquis and Marchioness of Bute. On August 5 the local committee will give a Welsh concert at the Park Hall. The members will be invited to luncheon by the Monmouthshire and South Wales Coalowners' Association on August 3, and by the president of the Cardiff Chamber of Commerce, Lord Windsor, on August 4. On the same day the members will also be invited to dinner by the directors of the Taff Vale Railway Company. The chairman of the local reception committee in Cardiff is Sir William T. Lewis, and the honorary secretary is Mr. T. Hurry Riches, M.Inst.C.E., of the Taff Vale Railway, Cardiff.

## NOTES AND COMMENTS.

It may well be asked when taste will determine the value of TURNER'S works less blindly. When within the past twenty years Sir JOHN PENDER gave about 8,000*l.* for four of the artist's paintings he was supposed to have purchased without discretion, yet on Saturday the four realised 30,345*l.* *The Wreckers* was exhibited in 1834. It was purchased by Mr. E. BICKNELL, at whose sale in 1863 it brought 1,984*l.* As on Saturday it was bought for 7,980*l.*, the value has quadrupled in a third of a century. Sir JOHN PENDER gave 2,000*l.* for *Mercury and Herse*, and it realised 7,875*l.*, or nearly four times his price. *The State Procession bearing Giovanni Bellini's pictures to the Church of the Redeemer, Venice*, which was exhibited in 1841, sold for 7,350*l.*, and another picture of that year, *Venice: The Giudecca, Santa Maria della Salute and San Giorgio Maggiore*, which TURNER valued at 262*l.* 10*s.*, reached 7,140*l.*, or over twenty-seven times the original price. The sale is creditable to the investors, but we hope it will not induce the world to conclude that modern pictures are an unprofitable investment. At the PENDER sale, MILLAIS'S *Proscribed Royalist* found a purchaser at 2,100*l.*, and JOHN PHILLIPS'S *La Gloria: A Spanish Wake*, was purchased for the National Gallery, Edinburgh, at 5,250*l.*

So much discontent prevails in Paris about the management of the Louvre and the operations which are performed on some of its treasures, especially important examples of painting, it is no wonder that a sort of protective association has been constituted. The new Société des Amis du Louvre is composed to a large extent of amateurs, but some of the officials have been invited to join it. It will correspond with the Rembrandt Society of Amsterdam. The committee appointed to make preliminary arrangements consists of the following members, viz.:—M. le Comte GREFFULHE, Le Comte DE CAMONDO, Le Baron EDMOND DE ROTHSCHILD, MM. MACIET, PUVIS DE CHAVANNES, DETAILLE, C. GROULT, TRÉLAT, DENYS COCHIN, EMILE MICHEL, BARDOUX, DERVILLÉ, BOURGEOIS, POINCARÉ, REDON. The ostensible object of the Society is to enrich the galleries, but a party so influential cannot fail to exercise supervision over conservators and assistants. There will be henceforth less grumbling over purchases of doubtful value and chemical experiments which deprive paintings of their most admired qualities.

THE Place de la Concorde in Paris is at night brilliantly illuminated, but it is desired to have it still more bright during the time of the International Exhibition. In the daytime the obelisk of Luxor is the most interesting object, for the statue of Strasbourg is not in a position which can vie with it. The question has been raised, Why should not the old Egyptian monolith become equally prominent at night? That end can only be accomplished by surmounting it with an electric lamp of great power. For that purpose it would be necessary to have wires or tubing along one or all of the faces of the obelisk. It is therefore proposed to drill a hole through the entire length of the obelisk and its pedestal, which together measure about 100 feet. In that way the hieroglyphics, which are gilded, would not be obscured. It is possible to make a passage for wires by improved drills without any injury to the stone, but will not the boring be to some extent an act of vandalism? It would, however, be in keeping with many acts of restoration in France in which the past was sacrificed to the present.

THE rules of the Science and Art Department concerning registration and grants for students' attendances in art classes have been recently altered. Last year it was stated that "the attendance grants are  $\frac{1}{2}$ *d.* to 3*d.*, 1*d.* to 4*d.*, 3*d.* to 6*d.*, or 4*d.* to 8*d.*, for each attendance in an art school or class, according to the subject or stage of subject. But no more than twenty attendances in any one subject or stage of a subject in art will be counted during one session on behalf of a student, or more than thirty altogether in the elementary stages of two or more subjects, or more than sixty altogether in the advanced stages or in the elementary

and advanced stages together of three or more subjects." This year the fees in Group II. have been increased from 1*d.* to 5*d.* The numbers of attendances for qualification are to be as follows:—"No more than forty attendances in Group I. will be counted during one session on behalf of a student, or more than sixty in one or more of the other three groups. But if Group I. be taken with the other groups, not more than fifty attendances can be counted altogether." Last year it was one of the conditions for obtaining a grant that the inspector should report "the class or classes are not too large for instruction by the staff of teachers." In the new regulations the clause is omitted. As long as the teaching and equipment are considered satisfactory there is no limit to the number of pupils that can attend a class.

THE Tudors are not favourites with the Manchester people, and beyond the wearing of rich costumes and the employment of an occasional painter it is not easy to discover what the family did to earn the admiration of Lancashire. The chairman of the art gallery committee is not satisfied with the indifference of the people to the exhibition which is now open, and he said on Wednesday that if the committee had to depend on Manchester for the success of the exhibitions they might as well resign their office. If they asked the people of Manchester to pay sixpence or a shilling to visit the autumn and other exhibitions they received no reasonable support. A great many of the visitors came from the surrounding towns, and the attendance, so far as Manchester was concerned, was of the most meagre description. The Tudor Exhibition contains much which is interesting, but the title is against it. Although there appears to be little interest in art, the committee considered they were justified to expend 1,600*l.* on a picture by WILLIAM MÜLLER which formed part of the Pender collection.

ANCIENT as is the Egypt of the history of architecture, there is another and much older Egypt, of which Mr. H. W. SETON-KARR has afforded a glimpse by means of the collection of prehistoric flint implements which can be seen at the Royal Archæological Institute. The majority came from flint mines in the Eastern Desert, at a distance of about thirty miles from the Nile. The workings were in some cases along ledges on the face of the cliffs; in others on level ground on the step-like tiers or plateaux which descend from the high, table-topped mountains to the dry sandy bed of the Wady-el-Sheik. At some of the mines were shafts about two feet in diameter, filled up with drifted sand, and surrounded by masses of excavated rock neatly arranged. There was usually a central work-place where most of the objects were discovered. But in some mines a number of clubs or truncheons lay distributed uniformly, as though hurriedly left when the mines were last abandoned, at a period probably long anterior to historic record. Many of the implements differ from those which have been found in Europe. Mr. SETON-KARR also shows quartzite and flint implements from Somaliland which are supposed to be of earlier date than any found hitherto in Africa. They were evidently buried, and suggest that they belonged to a more ancient race than any of those of which relics remain. Sir JOHN EVANS considers that they "have an important bearing on the question of the original home of the human race. Of their identity in form with some from the valley of the Somme and other places there can be no doubt, and we need not hesitate in claiming them as palæolithic. The cradle of the human race must have been situated in some part of the world where the climate was genial and means of subsistence readily obtained."

## NORWICH CATHEDRAL.—IV.

THE plates we have published will suggest that the main part of Norwich Cathedral, including the tower, may be described as Norman in style, the exceptions being the upper tier of windows in the choir and the vaulting. There are, however, accessories of a later time, the most important being the cloisters which are shown by the illustrations in the present number.

The cloisters were commenced during the episcopacy of Ralph de Walpole, which lasted from 1289 to 1299, when he was transferred to the diocese of Ely. At his consecration he was advised to avoid applying to his own use the firstfruits of the vacant benefices in his diocese, as was customary, and he consented to that reform. He commenced the cloisters at the north-east angle.

Richard de Uppenhall, the undertaker or builder of these works, erected three more arches or compartments on the same side of the cloister. The remaining five arches of the cloister on the east side, with the whole of the south walk, were built by Bishop Salmon and his friends. At this time part of the revenues of the monastery was applied to an officer called the *pittancer*, who being dispensed with, his salary, called *pittance money*, was expended on the new works. The cloister was continued by other patrons or contributors. Accordingly we find that the north walk attached to the wall of the church was erected by Master Henry de Well, who expended 210 marks on it, and twenty pounds more were given by John de Hancock. Bishop Wakeryng built the entrance doorway to the church at the north-west angle of the cloister, as well as a portion of the cloister at that part, and the remainder to the lavatories with some doorways were raised at the expense of Jeffrey Simonds, rector of St. Mary-in-the-Marsh, at an expense of 100*l*. The refectory, strangers' hall and other parts of the monastery were connected with this end of the cloister. In the year 1302 Walter de Burney, a citizen of Norwich, gave 100*l*. and much of the ironwork towards glazing the windows of the cloister. From the armorial bearings painted on some of these windows and sculpture on the ribs, &c., Blomefield concludes that the rest of the building was "finished by the several families of Morley, Shelton, Scales, Erpingham, Gourney, Mowbray, Thorp, Savage, &c., and thus this famous cloister was finished in the time of William Alnwyk, lord bishop here, and in the third year of William Worsted, prior of the church, who were both considerable benefactors in the year of Our Lord 1430, and in the 133rd year from the first beginning of the work."

Although the cloister was built at different periods, and by different persons, we find a general uniformity of style prevail in the details of columns, capitals and groinings, and even in many of the mouldings of the four sides. Yet by close examination a progressive change in architecture may be found in the tracery of the windows, commencing at the east end, and continuing through the south, the west, and terminating with the north. By the rabbits in the mullions of the upper part of this cloister, it is concluded that it was originally glazed. At the south-west angle of the cloister are two lavatories; and the whole roof is enriched with a great number and variety of sculptured bosses or orbs. Many of these are interesting as specimens of sculpture, and as representations of scriptural and monastic events.

The names of Bishops Salmon, Wakeryng and Alnwyk, as well as of Ralph de Walpoles, are therefore connected with the construction of the cloisters.

John Salmon was appointed by the Pope to this see in 1299, and proved an active and distinguished governor of the diocese. In 1303 he addressed an hortatory letter to the people of his bishopric, urging them to contribute to the repair of St. Paul's Church in London. On the death of Edward I. he received letters to pray for the health of the new monarch and prosperity to the kingdom, and soon afterwards was appointed one of the ambassadors to demand Isabel, daughter of the French king, as queen for Edward II. On January 18, 1307-8, he was summoned to attend the coronation, and shortly after was deputed, with several English lords, to wait on the Pope. In 1316 he was again sent to his holiness at Avignon, to pay one thousand marks pension for the kingdoms of England and Ireland. One of this bishop's letters is preserved in his own register at Norwich, dated from York, and complaining that he was obliged to attend the Parliament in that city and thereby incur an "insupportable expense and be unable to visit his diocese." Being highly in favour with the king and Parliament he was appointed Chancellor of England in 1320, and had the broken fragments of the old great seal allowed him as his fee. After fulfilling the duties of many distinguished offices he died at Folkestone Priory, in Kent, July 6, 1325, and his remains were conveyed for interment to his own private chapel at Norwich. Besides this building he erected the greater part of the charnel chapel, the hall in the palace and the north walk of the cloister.

John de Wakeryng, born at Wakering, in Essex, was one

of the Privy Council to King Henry VI., Lord Privy Seal and Lord Keeper of the Great Seal, before he was advanced to the See of Norwich. Immediately after installation he constituted John, Archbishop of Smyrna, his suffragan, with full powers to "consecrate and reconcile, or reconsecrate churches, churchyards, altars, cups, patins, corporals, vessels, vestments and other ornaments, and to confirm and confer the clerical tonsure on learned men, and to ordain to all orders, during the bishop's pleasure." About this time there was a great struggle for the Papal See by three different persons, who referred their respective claims to the pontifical throne. A Council was called at Constance to settle this dispute, when many of the English nobility, clergy and gentry, to the amount of 800, were deputed to attend the meeting. Bishop Wakeryng was one of the number, and was nominated with five others to elect the Pope. Martin V. was chosen; and the conduct and ability of Wakeryng excited the approbation of the assembly, and induced the Pope to ratify his confirmation and consecration free of expense. Though our prelate obtained the character of "a pious, chaste, bountiful and affable person," yet he was intolerant towards the Lollards, and carried his persecution to a great extent. He built a covered way or cloister from the palace to the north transept, also a chapter-house, and after governing the See nine years died in 1425 and was buried on the south side of the altar-steps.

William Alnwyk, or Alnwyke, a native of Alnwyk in Northumberland, was appointed the first confessor and priest to the nunnery of Sion, Middlesex, and was afterwards made Keeper of the Privy Seal and Confessor to Henry VI. After being installed in Norwich Cathedral, December 22, 1426, he directed his attention to the repairs and embellishment of his church and palace, and built the western doorway with a window, &c., to the former, and commenced a tower gateway to the latter. He presided here ten years, and was then translated to Lincoln, where, and at Cambridge, he is said to have executed some architectural works.

## SIR JOHN SOANE'S MUSEUM.

ACCORDING to the report for 1896 the tendency to improvement recorded in 1895 in the affairs of Sir John Soane's Museum has been steadily maintained and further augmented. Had it not been for the exceptionally wet and unsettled weather which distinguished the autumn of last year, a much larger attendance of the general public would probably have been recorded. The very slight diminution in numbers was due and attributable solely to that cause. In 1894 the number of visitors was 3,512; in 1895 the number of visitors was 4,940; in 1896 the number of visitors was 4,860; while the number of students for the same years was 12, 107 and 209. These figures are a proof that Sir John Soane's noble gift to the nation is becoming better known and more fully appreciated by those for whom it was primarily intended.

With the permission of the trustees the museum has been thrown open on Saturday afternoons to various clubs, technical classes and institutes, the various societies having the museum and its contents described to them by the curator. This privilege seems to have been so very fully appreciated that in several cases the members asked to be allowed to pay a second visit; about nineteen different societies availed themselves of this permission.

In classifying the various nationalities among the general public, the United States of America head the list with 287; France, 51; Germany and Austria, 38; Belgium and Holland, 18; Italy, 13; Russia, 5; Norway and Sweden, 8; Denmark, 3; Brazil, 3; Armenia, 2; Canadians, Australians, South Africans and other colonials are included with ourselves. On students' and private days the museum is practically never closed, for all foreigners and strangers in London are invariably admitted on presentation of their cards, while the general public have but to write for tickets, and they can also view it on closed days, but as there are no attendants present during the period the museum is closed to the public or on private days, it is necessary to give sufficient notice to the curator.

The funds by which the museum is maintained were settled by Act of Parliament in the lifetime of Sir John Soane, and at the time were fully sufficient to permit a small surplus being invested each year so as to form a reserve or building fund, in case of repairs, painting, &c., but the heavy increase of rates and taxes and the consequent diminution of the revenue by the change of the rate of interest on Consols from 3 per cent. to 2½ per cent., in addition to the extra expenses for attendants involved by opening the museum to the public four days a week instead of two, and six months in the year instead of three as originally settled by the Act, make it necessary to be economical in the management of the trust, especially as a further reduction of income will take place in a very few years when Consols will drop to 2½ per cent.

The balance at the end of 1896 being exceptionally larger in

consequence of the long-deferred payment by the London County Council of the compensation money for the loss of the freehold rights in the Lincoln's Inn Gardens enclosure, nearly two years after the Council obtained possession, has been partly expended on providing artificial light, so that on dark days during the winter months the collection can still be seen, which before was almost impossible. In the *personnel* of the museum great changes have taken place during the past year. The trustees have lost three of their most distinguished colleagues by death and one by resignation on account of ill-health, viz. Lord Leighton, Sir John Everett Millais, Bart., Sir Benjamin Ward Richardson; Sir William Flower, K.C.B., wishing to concentrate his remaining energies on the Natural History Museum, South Kensington, has resigned the trusteeship he held for over fifteen years. In their places Sir Edward J. Poynter, president of the Royal Academy; Sir George M. Birdwood, K.C.I.E., C.S.I., and Professor Arthur H. Church, M.A., F.R.S., have been elected. With such trustees, in addition to those who have been identified with the trust for many years, there is every guarantee that Sir John Soane's museum and library will prove to be a most useful institution for those of the student class in either arts or literature who choose to make use of its treasures, a class for whom, rather than the general sight-seeing public, Sir John Soane founded and endowed it.

### PLUMBING AND SANITARY WORK.\*

(Concluded from last week.)

**I** NOW come naturally enough to valve-closets, the prince of water-closets for private use and for places where such a convenience is not used for several days together and when the supply of water is not limited to two gallons. The "Bramah" valve-closet was invented by Joseph Bramah, of London, in 1778, but it has been much improved upon since then, especially during the last ten or twenty years. In turning out some drawers recently I came across a printed circular of a valve-closet by the founder of my business, which was established upwards of a century and a half ago, and I have thought it of sufficient interest to reproduce upon the screen to-night for you to see. It was printed by T. Bensley in about 1790, I think. His printing press was next to Dr. Johnson's house in Bolt Court. If you look at the type you will see that the long S is used, and the Caslon foundry abandoned that form of letter in 1785.

The illustration shows a D-trap under the closet, but according to the text this trap was at that time called an "air" trap; and although they seem to have preferred that its position should be immediately under the floor of the closet, they do not seem to have been very particular about this, for in the directions for fixing it is specified to be "fixed under the floor of the closet, if the joists are of sufficient depth to allow it; if not it may be fixed at the bottom of the funnel-pipe." It is interesting to notice that at this time soil-pipe was called "funnel-pipe"—the name by which it is still called by some old plumbers—and, what is still more interesting, as shown by the circular, the conservatism of that day was very strong, for they stored the sewage in cesspools built at the bottom of funnel-pipes inside their houses. But they saw a danger in this unless matters were well suppressed, for the specification states that "great care must be taken to make properly good round the bottom of the funnel-pipe where it enters the drain or cesspool, so as to entirely prevent the foul air from being emitted." There is nothing said about the ventilation of the soil-pipe or of the cesspool; the authorities were content to "bottle up" such matters, and there was wisdom in this with so much storage of sewage in closet-trap and cesspool.

But I must return to my subject. I have called the best kind of valve-closets the prince of water-closets, and I have done so because I know of no other which embraces so many good points. It has a larger and a deeper body of water than any other closet for receiving a motion, submerging it and carrying it away in what I have called elsewhere a water-envelope, whilst the valve which keeps the water in the basin enables its sides to be so extended that they are practically protected from the dejecta, no matter what state the body may be in. And to protect the flushing-rim of water-closets I have recently introduced a receding-rim.

Then, with the attached supply-valve, at the same moment of time the closet is discharged a very vigorous flush of water is made to cleanse the whole of the interior of the closet together with its trap; and not only so, the sides of the basin are rinsed down at the same time, so that not a vestige of foreign matter may remain behind.

Then the valve-closet is superior to all other closets, whether of the "wash-out," "wash-down" or "syphonic" kind, in that

its basin water—the water which is open to the apartment and the house—is separated from the water which stands in the closet-trap, in fact is "disconnected" from the water which is exposed to the air in the soil-pipe, as shown in section upon the screen, which is an illustration of a valve-closet which I have had specially made for fixing upon fireproof floors and places where it is desirable that the floor under the closet should remain intact.

There is also another great advantage attending a good valve-closet, viz. with an efficient lead trap under it having a wiped soldered joint to the lead soil-pipe there will ever be a reliable connection with the soil-pipe, and a reliable water-seal; so reliable that the trap and its jointing may be depended upon for many generations.

In the case of earthenware closets with earthenware traps in one piece—the pedestal kind—or in two pieces, it is not so; for there is not only the risk of a breakdown of the connection with the soil-pipe, but there is also the risk of the breakage of the closet itself, its trap or its basin part, which would mean a defective water-seal or no protection at all from the soil-pipe air, pending the changing of the closet for a new one.

I know that some authorities have been content to fix valve-closets without a trap between the closet and the soil-pipe, but it is astonishing what may be done in the name of sanitation. Now, though something may be said in favour of fixing a valve-closet without a trap on a very short length of soil-pipe, which has its discharging end open to the air, what can be said in favour of such a closet fixed upon a long length of soil-pipe into which other valve-closets discharge with no trap to any of them? And yet scores have been so fixed. Only within the last few months I know of such cases where the closets have had to be resanitated.

I will not insult you by arguing in favour of fixing traps under water-closets—that is a sound principle conceded by us all; but I shall be glad of your attention whilst I demonstrate the fact that a round pipe-trap—the syphon trap, the kind often fixed in ignorance of its behaviour—under certain circumstances loses its water-seal, and for a time ceases its work of safeguarding the house from the soil-pipe, and perhaps the drain as well. It seems a waste of words to say that if a trap be necessary at all it should be of that kind which could be relied upon under any condition to which it would be liable.

With a round-pipe or syphon trap the discharges pass through it in so unbroken a form and with so much momentum, gained in the fall from the closet-basin, that the combined action of syphonage and momentum is not arrested in time to leave sufficient water in the trap to reseal it.

With an "anti D-trap," as I shall show you by one or two tests, the water is just sufficiently broken up at the outlet of the trap to retard both the action of momentum and syphonage, for insuring the retention of an efficient water-seal, no matter how small or how large a body of water may be sent through it, whilst to insure an entire change of the previous contents of the trap its body part is purposely made smaller than its inlet, and as it holds about 40 per cent. less than a 4-inch syphon-trap, I need hardly say which is the more wholesome of the two, although both kinds may be considered as self-cleansing. By the favour of the Worshipful Company of Plumbers I have here an apparatus which the Company fitted up at King's College in connection with their museum and workshops—those for the extension of the technical training of student plumbers. I have had a photograph taken of the apparatus, and before demonstrating will show it upon the screen.

Next to the importance of an efficient trap to a water-closet is an efficient water-supply, for the best closet in the world may not only be marred, but may be ruined by the want of either. To expect two gallons of water to carry a motion through the closet, trap, branch soil-pipe, the vertical stack, and a long length of branch drain to reach the main carrier, and not leave a vestige of filth behind, is expecting too much. The fact is, if the water flush is to be efficient, it must be made to depend somewhat upon circumstances, upon the necessities of the case, and that only where water is scarce, or where it is imperative to economise its use in order to maintain a general supply to the house, should it be limited to two gallons.

Two gallons of water with an efficient flushing-cistern may fairly suffice for the best kind of wash-down pedestal closets with small water areas, when they are situated near to the main carriers with a general flow of water in them, or into which copious flushes are automatically and frequently delivered. But two gallons of water are insufficient for water-closets which hold a good body of water, especially when they stand or are fixed at any great distance from the main drain, that is, if the soil-pipes, drains and ventilating-pipes are all to be kept clean and wholesome. In my own house—I pay by meter—I have valve-closets for the best closets, with the water supply so arranged that each user may give a flush of two, three, or four gallons very rapidly and at pleasure, and during the thirteen years that I have occupied the house I have never had to pay extra on that account. I say this to encourage water companies in giving a larger license to consumers.

\* A paper read before the Architectural Association by Mr. S. S. Hellyer on May 21.

As only, however, two gallons of water are allowed by most companies, it is most important that this quantity should be utilised in the best possible way, and as there are flushing-cisterns and flushing-cisterns only the most efficient should be used. You all know well enough what difference there is in their discharging power; I have here one taking not quite five seconds to discharge, the size of the flushing pipe being 1½-inch and the cistern being nearly noiseless. With a noisy advertiser in a house, it is vain for any person to pretend he only left the room to get a pocket-handkerchief. Such fittings are most unpleasant to retiring dispositions, and they ought not to be fixed in private houses. I was dining a month or two ago at a friend's house, and wishing to give a second flush to the closet I waited four minutes by my watch for the flushing-cistern to fill; when I left it was still filling, and I dare say by this time it is filled ready for the second flush.

A properly fitted valve-closet with an attached supply-valve and bellows regulator is the least noisy of all water-closets, and when it is so fitted up that the lid of the enclosure can be put down before the handle is pulled, it is practically noiseless in its action. The next slide will show a view of such a closet. It is so arranged in my house, where, for the sake of convenience and for good general flushing when necessary, the service to it is taken from the general service pipe to other fittings. When this is properly done I do not see how any contamination can take place, but as it is most difficult to always rely upon things being properly done, it is better to separate the water-closet supply from all other services. When the cistern for this purpose would have to be fixed in the water-closet apartment it should be kept as small as practicable, holding only about half a dozen gallons of water, so that its entire contents may be frequently changed, for, notwithstanding any lid it may have, the effluvia of the apartment would gain access to the water and taint it. Where a good flush is desired, and the head of water would be under 5 feet or 6 feet, the service-pipe to the closet should be of 2-inch bore.

If we were not influenced by fashion or carried away by the current of things, I should wonder much why pedestal closets with narrow ring seats ever came into vogue for the best closets in private houses, especially for ladies' use, for I suppose the least observant must know that it is cleaner and nicer for a lady's dress, especially with a long skirt, to rest upon the dusted seat of an enclosure rather than upon the floor, remembering what closet floors are like at times. With a table-top closet basin protecting the enclosed space, and with an air-tight joint to the top of a nicely-fitted enclosure, as shown upon the screen, not only is the vapour excluded from the space inside the enclosure, but dust and the sweepings of the apartment as well. And with such an arrangement no cold draughts can blow upon the person using the closet. And even for the use of men, when they are feeble and advanced in years, a table-top pedestal closet affords better means for raising themselves from the closet than the ring-seat, allowing them, as it does, a firm place to rest their hands upon, as shown by the closet illustrated upon the screen.

Before leaving the subject of water-closets, I ought to say something on the apartments in which they are fixed, though there is no time for more than a word or two. The apartment in itself, apart from the closet, may become an accumulator or disseminator of disease. Dark and dangerous water-closet apartments may be found with the aid of a candle in the interior parts of old mansions with no natural light or ventilation. The vapour generated in them or escaping from the closet apparatus may be as difficult to remove as air out of a bottle.

One side of a water-closet apartment should at least stand next the external air, having a window in it reaching up to the ceiling, as was shown in the last slide but one, and as is shown in this case also. Where it would be much used it should be provided with independent ventilation—should have, in fact, an air inlet and an air outlet.

It is important that the walls and ceiling should be made practically air-tight, and that there should be no places or parts about them where dust could collect and accumulate. And in public water-closets, and in water-closets which would be liable to be used as urinals, the floors should be impervious.

For the best water-closets with enclosures, as just shown, and for table-top valve-closets in private houses and important positions, a floor of solid marble from wall to wall, or to a point 6 inches or so beyond the sides and front of pedestal closets, is very desirable, as shown. The marble is sunk a little to catch any little leakage of the supply-valve, should such ever occur, and carry it away by an overflow pipe being fixed to the floor, and discharging into the open air. Where marble cannot be afforded the boarded floor inside the enclosure should be protected by a lead safe to which the lead trap under the valve-closet should be soldered. I should just say here that the overflow pipe from the safe being a clean water-pipe can be utilised for introducing a constant stream of fresh air into the apartment; but when this is done in exposed positions, the grated opening in the marble floor should be kept outside the enclosure,

so that the incoming air, when frosty, may not come directly in contact with the service-pipe, service-valve or closet-basin.

I now come to soil-pipes. According to the by-laws of the London County Council, under seal dated June 1893, all soil-pipes in buildings erected after that date are to be outside. Now, although I have done, perhaps, as much as anybody to encourage the fixing of soil-pipes outside, and still prefer such pipes to be outside, I have never slavishly chained myself down to such a restriction, and I think it is a pity the by-law should be so stringent, or that architects and plumbers should be so hampered, for it requires no great imaginative power to conceive of circumstances where the disadvantages would be greater than the advantages.

If it is a question of durability and sanitariness, in certain cases a soil-pipe fixed inside a house would be more durable and more sanitary than if fixed outside.

When they are situated on south fronts, where no shadow protects them, they often become so hot that the naked hand cannot be kept upon them; and their variation in temperature, from mid-day to midnight in the summer months, would be three times greater than upon pipes fixed inside or with a northerly aspect. The strain upon the joints of iron pipes, and the unequal expansion and contraction of lead pipe, would tell much upon their durability. And of course in such cases sewage matters would adhere and dry upon the soil-pipe in a different manner to that upon a pipe which did not become so heated, and it would, therefore, be less sanitary, unless, indeed, the water-closets upon it were well flushed at every usage by more than the water companies' restricted two gallons.

Then in certain cases it is most difficult to find a good course for an outside pipe, free from a doorway or a pilaster, free from mouldings and enrichments; difficult to prevent it disfiguring the building. Of course I am sensibly alive to the fact that such pipes may often be made to improve the elevation, but that they are always so treated I will not attempt to prove to this Association. So ugly are they at times that one fancies they must lower the value of the property on which they are fixed. I have had some photographs taken of a few such, and will show some upon the screen. They are to be seen here, there and everywhere in hideous fashions, being fixed neither vertically nor horizontally, nor in any pleasing line, crossing chimney-breasts, coming out over stringings, cornices, roof gutters and parapets, going up to the roof over all the obstacles of their course victorious.

Then often no attempt is taken to disguise their purpose. Branches from water-closets are brought out, and carried along on the face of the wall to the main pipe; whereas a little alteration of the water-closet apartment, or a little shifting of the water-closet, or a little graceful bending of the main pipe, or a dexterous treatment of the branches, and they could have been brought through the wall, and soldered to the back of the pipe, where they would never be seen. The poor arrangement now shown is a photograph of such a pipe, showing its ugly advertising water-closet branch as recently fixed on the face of a house in one of the best streets in the medical world. I will now show you a stack where the branches are brought in at the back of the pipe, and though it was fixed ten years ago you will see how well it stands and how well it looks—the photograph of this was only taken the other day.

Now as to the material of which soil-pipes should consist. For my own house, though I were as rich as Croesus, I should be content with lead pipe, and I should prefer it to any other kind of pipe that I know. I should be satisfied that the pipe was more wholesome than iron, being easier cleaned and more durable, being less corrosive, and that its wiped soldered joints could be more relied upon than even the caulked lead joints of cast-iron pipe, and remembering that they are much fewer in number, there being at least two more joints with iron pipe than with lead in every closet branch. In fact, when the main pipe is of iron and the branches of lead there would be four joints to every junction, as shown, for the London County Council rightly enough require such connections to be made with a brass ferrule, as shown, on the face of the external wall. But whether the branch be of lead or iron the joint with the iron junction should never be allowed to come into the wall, as shown in the next photograph. Then, with iron pipe there would also be more joints on the main pipe, lead pipe being made in 10-foot or 12-foot lengths to suit circumstances, and the iron pipe as generally used in 6-foot lengths.

Then the character of lead pipe compels the plumber to connect the ends neatly and nicely together, if he is to make a well-wiped soldered joint upon them, and with such yielding material as lead he has no difficulty in doing this, for he can bend or boss or alter either end at will, and rasp them to a great nicety; whereas, with a rigid spigot or socket end of a cast-iron pipe, what can he do when the two pipes do not come together in true correspondence in their interior surfaces, or when he has been a little out in his measurements? The pipe may be a little too long or too short, but he cannot alter the socket, nor can he tamper with the spigot without destroying the bead or shoulder which is to keep the caulking material

from getting into the interior of the pipe. Indeed, he may aggravate the case in caulking in the lead by shifting the upper pipe away from its true bore with the lower pipe, and so leave a shoulder inside for matters to catch and collect upon. At any rate, such connections often afford places for particles of filth to accumulate in, and though this may not mean much in one joint, in the aggregate—in the tens of thousands of joints—if all the soil-pipes of a large town or city were of iron, it would mean something. I mean that a stack of iron soil-pipe with several water-closets upon it would not be so free from smell as it would be if it were of lead with precisely similar closets and water flushing.

In my house in Newcastle Street there is a stack of 4-inch soldered seam lead soil-pipe which was fixed more than a century ago, and I see no reason why it should not last as long again. It is made of cast sheet lead about  $\frac{1}{4}$  inch thick, and for you to see its present condition I have had two pieces cut out of its lower part and photographed. The piece showing its exterior is splashed over with the many whitewashings given to the cellar during the century, but as you see, the pipe is quite sound and good, and fairly clean in its interior, as shown by the other piece. A Bramah closet, similar to the one shown earlier in the evening, discharged into it on the second floor, and was, I expect, in daily use for three-quarters of a century, when it was changed, together with its D-trap, for a "Vortex" closet, since when it has only been in use six days out of seven. It is interesting to know that the apartment, though well lighted, has only a borrowed light, viz. through a glazed fan-light and semi-glazed door, both of which open into the staircase for access and ventilation, just under a well-ventilated lantern light.

But we all know how well lead pipe stands the London atmosphere. I will show you a photograph of a lead R.W. head and pipe which was fixed on the old dining-hall of Staple Inn in 1655, and also of another head and stack which was fixed on the Chambers in the same Inn in 1729, both being in very good condition to-day. I will also show you a photograph of a stack of lead soil-pipe fixed in 1881, and that of another fixed in 1888, both being straight and good to-day and showing no sign of deterioration.

To prevent sagging and "telescoping," lead soil-pipes should be well supported about every 5 feet with a pair of tacks, and the strength of the pipe should be equal to sheet lead weighing 8 lbs. to the superficial foot.

For every unsound soldered joint on lead soil-pipe I should expect to find a thousand unsound cement joints in cast-iron pipe, and even when a joint is made with great care in iron pipe after a time it is liable to breakage by the expansion and contraction of the pipes as shown. The pipe generally used is of insufficient strength and is liable to fracture like that shown, which also shows a defective joint with its fellow pipe and with that of the drain.

But I have no desire to unfairly decry iron soil-pipe, especially when such pipes are of good strength ( $\frac{1}{4}$ -inch metal for outside situations), and the joints are well and carefully made with blue lead or Spence's metal. In fact where hot-water is discharged into a soil-pipe, lead pipe with soldered joints would not stand the continual strain of expansion and contraction, and therefore iron pipe would be much preferable in such cases. But, in my opinion, hot-water ought never to be discharged into soil-pipes; their temperature should never be so raised. I know well enough that in America not only are the baths and lavatories discharged into soil-pipes, but also the sinks; but we can afford to treat plumbers' work more sanitarily; we can carry the waste-pipes from such fittings through the open air and discharge them into intercepting-traps, for we are not subject to such severe frosts.

All soil-pipes, no matter of what material they are made, should be carried up at least full-bore to the highest parts of the roof, where the air coming out of them would have no chance of getting into the house, and where the wind from any point would blow over them to carry the bad air away. I think it is only right to say that this matter is now much more considered by the authorities than used to be the case, but I am going to show you directly a few instances of bad treatment where the pipes have been recently fixed, some even this year. The photographs will be sufficiently graphic to need no words of mine to point out the evils. It will readily be seen how the emanations of soil-pipes and drain ventilation-pipes can contaminate the cistern-water or enter a house through its windows or chimneys; and how even though the people of one house may be friendly and neighbourly enough on the lower part of their houses, they are not really so in the upper part, the air from the soil-pipe of one house being allowed to enter the window of the other house and poison the air within, as shown in the illustration.

Now, as to the size of a soil-pipe. Before determining the size of the pipe, it is important to know what it has to do. In addition to its work of carrying away the discharges of a tier of water-closets, it has also to act as a ventilator to the drain, it ought not to be less than 4 inches. And if no syphonic action is to take place in it, that is if no anti-syphonage pipe is fixed

to its trapped branches, it should be of larger bore still—5-inch or 6-inch pipe. And even this size would not be large enough to prevent syphonage when the air had to come down a long length of piping, as in the case of a very high building, unless its upper part—the ventilation pipe—was of a bore still larger, for the air to pass down the pipe free from friction and in a body sufficiently large to prevent a vacuum.

When no anti-syphonage pipe is fixed, and the main soil-pipe is only  $\frac{3}{4}$ -inch or 4-inch bore, it is of paramount importance that only water-closets which have special traps should be fixed, which means a deeper seal and a larger body of water. Now, except in the case of valve-closets, as we have already seen, the water-seal of a closet is in open contact with the air in the soil-pipe and the drain, and where the closet is not in constant use the water held in its trap would become tainted and surcharged with gases. It is, therefore, important that the whole of this water should be changed every time the closet is used, and I confess that I do not see how this is to be done satisfactorily with a two-gallon flush, if the water-seal of the closet-trap is to be of a depth great enough to withstand the action of syphonage without the aid of an anti-syphonage pipe, and the closet is to be left with its full water-seal.

Moreover, without anti-syphonage pipes there would be no ventilation of the closet branches, no matter how long they might be. In fact, such branches would be like inverted bottles, for there would be no escape for the gases in them, except by diffusion or by passing through the water-seals of the closet to the house.

To show the power of such pent-up gases I have had a lantern slide made of a photograph which I had taken the other day of the interior part of a piece of lead pipe which was branched into a stack of soil-pipe about fifteen years ago. As you see the lower half, which carried off the matters sent into it, is practically intact; but the upper half, the part exposed to the gases and vapour, is eaten through in many places. The main soil-pipe on which it was fixed was open full bore to the air about 50 feet above it, and for a few years it was trapped off from an old drain with which it was connected, when it was reconnected without a trap to a system of drains which had several other open soil-pipes upon it for ventilation. The piece of lead water main shown in the photograph has nothing to do with it. It is, as you see, quite perfect, though it is supposed to have been in use at Hampton Court Palace 350 years. It will be found with an anti-syphonage pipe of 2-inch bore that a  $\frac{3}{4}$ -inch or 4-inch soil-pipe will answer very well for a tier of many closets, except in the case of very high buildings. And as the London County Council allow nothing smaller than  $\frac{3}{4}$  inches and require 4 inches when it is connected with a 4-inch drain, I say nothing about smaller sizes.

I have no time to add much to what has already been said or implied on ventilation. The ocean of air surrounding every house ought not to make it too difficult to give full and free ventilation to every soil-pipe, waste-pipe and drain, and in such a manner that no air coming out of either outlet or inlet of the system should enter the house or be breathed before it has been well broken up and purified.

When many stacks of soil-pipe are directly connected to one large system of drains, having only one low-level inlet upon it, viz. at its "disconnection chamber," with the sewer, the several stacks will not have such currents of air in them as they would if each drain into which each stack discharged had its own independent inlet, especially when all the stacks are of equal height, and the air in them is about equipoised, though there is generally some different influence acting on one pipe more than another, difference of temperature, wind or weather. When no such influence exists the vapour will at times go up and down the pipes for hours together in a sort of seesaw movement. Backwards and forwards in the dark drains the injurious microbes may move, playing a sort of hide-and-seek; for I know little of their behaviour and less of their habit, except that I believe that light is not conducive to their longevity, and that fresh air annihilates them. But I must mind what I say, for are we all not made up of microbes? So I say no more on ventilation, except to remind you that, like money, there can rarely be too much of it where it is most needed. I have had some photographs taken of badly-positioned ventilating terminals from soil-pipes and drains, and will show them upon the screen, pouring their emanations into windows, cisterns, chimneys, &c.

Knowing that our time to-night would be too short to cover the whole field of sanitary plumber's work, I thought it better to pretty closely survey the parts looked at rather than give a galloping glance over the whole area. I shall therefore only call your attention to but one or two matters more.

The by-laws of certain district councils require the waste-pipe from every bath, sink or lavatory, the overflow pipe from any cistern and from every safe under any bath or water-closet, and every pipe for carrying off waste water, shall be taken through an external wall and discharge in the open air over a channel leading to a trapped gulley grating at least 18 inches distant; that is, such authorities prefer insanitary methods to

sanitary ones, for such treatment is sure to lead to a nuisance in some such way as shown by the slides taken from two original photographs.

Soap-suds and bits of soap will generally be found decomposing and throwing off bad air, and often bits of paper, orange peel, hair and the like will also be there, blocking up the grating, offending the eye and needing almost daily attention to keep clean. The ground, too, surrounding such gullies will often be found to be quite sodden with splashings and overflows. Whereas with such waste-pipes made to discharge into self-cleansing intercepting traps just under the grating no mess would be made, and no attention needed to keep the surroundings clean. And when such waste-pipes were properly trapped and ventilated, their air disconnection would be all that could be desired. I will show the two methods.

No doubt some years ago there was a reason for keeping the discharging ends of the waste-pipes well above a gully when the latter was generally a little cesspool in itself, and when waste-pipes were often fixed without traps, in which condition they acted as ventilators to the house. But no such reason exists now that self-cleansing intercepting traps are generally fixed, and that the waste-pipes are trapped. And yet only the other day a Board surveyor, against his own judgment, caused some waste-pipes to be altered because they delivered under the grating of a drain-interceptor instead of over it; that, too, notwithstanding the fact that each waste-pipe was trapped. A soil-pipe may discharge directly into a drain which may have no air disconnection within several hundred feet of the soil-pipe, although there be but the water-seal of the closet trap between the drain and the house; but for a waste-pipe to have its air-disconnection under a grating—oh, blissful ignorance.

No sink, bath, lavatory or other fixture through which dirty water may be emptied should be fixed without a trap of a self-cleansing kind, and one that will, when properly ventilated, retain an efficient seal, no matter how large the body of water may be which is sent through it. And to prevent the discharges of one fixture backwashing up into the waste-pipe of another and fouling it, each fixture should have its own separate trap, which should be situated as close to it as practicable, so that the piece of outlet pipe, standing between the house and the seal of the trap, may be as short as possible. I have so good an example of the very reverse of this that I have had it photographed for you to see. It is a 9-inch D, with no less than seven waste-pipes connected with it. Less than a year ago it was doing duty in one of the greatest university colleges of the country, receiving, as it did, the waste-pipe from a cistern, a bath, a drip-sink, a lavatory, a bath safe and other pipes.

As only a very short length of unventilated waste-pipe is sufficient to cause syphonage, the upper ends of such pipes as well as their discharging ends should be carried through the external walls to the open air. To show how small a fall suffices for this, I have here a little lavatory with 1½-inch syphon-trap and a short length of 1½-inch waste-pipe, with its discharging end standing only a little below the bottom of the lavatory trap, and yet the drop is sufficient to set up syphonage and to leave the trap practically unsealed with but a small discharge from the basin.

I was staying at an hotel in Germany last year, and noticing a horrible smell in a lavatory more than once, I searched out its cause and found that the lavatory trap was most easily syphoned, in a similar manner to that just demonstrated; for although it was connected with a soil-pipe, the latter was about 7-inch bore and could not, therefore, have caused the syphonage. It arose from its own unventilated waste-pipe.

Opening up the upper end of a waste-pipe to the air not only prevents syphonage, it also ventilates the pipe and keeps it wholesome. Where more than one trap is connected to a waste-pipe, through which quick discharges may pass, it is not sufficient for the upper end of the main pipe to be carried through full bore to the open air to prevent syphonage; each individual trap must be ventilated—must have an anti-syphonage pipe, in fact.

I think most authorities are now alive to the value of providing quick discharging arrangements to baths, sinks and lavatories, though only the other day I came across a small washhand-basin which took nearly one minute to empty. A 5-feet 6-inch bath ought to empty under two minutes, and where it would be in daily use, and was situated near the head of the drain, as the chief means of flushing it, it might be made to empty in one minute, a 3-inch waste valve being fixed to the bath for the purpose, and the trap and waste-pipe of equal bore.

I have no time to say more than a word or two on drains. When circumstances require a soil-drain to be fixed inside a house or outside it, where a leakage from it would find its way into the house or under the footings, I should strongly prefer it to be of cast-iron, with caulked lead joints, rather than of stoneware—whatever kind of joint may be adopted—the thickness of the cast-iron pipe being not less than ¾ inch in its thinnest part for 4-inch or 5-inch drains, and greater still for larger drains.

I know that some authorities still prefer stoneware drains to iron, even for fixing inside a house. I had an argument with

one only last year, but "a man convinced against his will is of the same opinion still." I think it would be almost impossible to find anywhere a stoneware drain of any great length inside a house absolutely water-tight from end to end which has been in use for, say, fifteen years. Even when every precaution has been taken and a stoneware drain has been very carefully laid and its joints specially made, one could not be certain how long it would remain perfect. After many years of existence there may only be a slight leakage in it, but if that occurs inside a house it will be sufficient to create great unrest in the minds of sensitive inhabitants, even if no illnesses arise from it. And the misfortune in such cases is that such leakage or leakages are generally difficult to repair, and are practically impossible of repair without danger of doing further injury to the drain.

I have just had a cast-iron soil-drain examined which was fixed inside a house in the City twenty-six or twenty-seven years ago by my firm. The pipe is of water-main strength, and is suspended from the ceiling joists in the basement. Both the pipe and the caulked lead joints were found in excellent condition, nothing having been done to them from the time they were executed, except that in whitewashing the basement the drain had also been whitewashed from time to time.

In 1881 I had some manholes built in brick and cement on the first floor of my offices as examples, together with some sanitary fittings and a specimen length of iron drain. I had a photograph taken of certain parts before their removal last year, and you will see that the iron pipe and the caulked lead joints are quite good and show no signs of wear, though they were experimented with for fifteen years. Also you will see from the same photograph, that though apparently no action has taken place between the lead and the Portland cement which connected a piece of lead soil-pipe to the stoneware drain, the cement joint shows that there was no real adhesion of the cement to the glaze of the stoneware socket, and this accounts for the leakage which quickly showed itself when tested with water.

Notwithstanding that many authorities require that even cast-iron drains should be embedded in concrete, I consider such treatment a wicked waste of money, for with a pipe of proper strength all the support it needs is from its under-side, except in very exceptional cases, and this is best done by brick piers built on concrete bases, with a stone or concrete resting slab for the pipe to nicely fit in, or by making a continuous bed for the drain in Portland cement concrete. This arrangement readily admits of the removal of the earth surrounding the drains and the joints, for any future examination of the pipe, and for recaulking of the joints when necessary. When such drains are encased in concrete, the cost of cutting away the concrete to find out a leakage or to get at the joints would lead to great expense and do damage to the drain.

Where practicable, instead of laying an iron drain in the ground, where it is inside a house, it is better that it should be carried on the face of some wall, or be suspended from a floor, or be carried in a subway, or have a tunnel or creeping trench specially built for it, in brick and cement, with openings into it only from the external air, so that the drain may be readily examined, and in the latter case be completely isolated from the house.

The many improvements in sanitary plumbers' work which I have brought before you to-night, or to which I have alluded, as well as many others which I have had no time even to mention, have almost entirely been made during the latter half of the long and magnificent reign of Her Majesty, whose Diamond Jubilee we are going to so gloriously celebrate next month. And when dipping my pen into the ink-bottle to write the finishing words of this paper, it occurred to me that instead of attempting any kind of peroration, the better thing to do would be to drop the pen for the pencil, and portray in a sort of transformation piece the progress of plumbers' work between 1837 and 1897.

Before showing this set-piece, which my draughtsman has so well got out, I should like to remind you of the great power you possess for raising and maintaining the standard of plumbers' work. Other authorities may desire it, may even expect it, but architects, from their privileged position as advisers, and as the designers and directors of building works, can demand it—can to a large extent secure it—by providing for it in their specifications, and by being prepared to properly pay for it. And though plumbers may not everywhere throughout the country be equal to the demand for very high-class work, they will be much stimulated by the desire of architects for such work. At any rate, more than any other class, more even than medical men—who have so nobly and so disinterestedly done so much for the craft, for sanitation—can the architect aid the plumber in making our homes healthy to live in.

When the handworker—greatly interested in his work—produces with skill and intelligence what was required of him, what was portrayed to him by the headworker, he is ever so much helped by some appreciative acknowledgment, however slight; and a word of praise to the deserving—how good it is. Like mercy, it is twice blessed. Gentlemen, in your works may it be your privilege to make the workers happy in their work.

## AMERICAN COUNTRY HOMES.

EVERYTHING in nature seeks in its environment, says Mr. H. Neill Wilson in the *Engineering Magazine*, the shelter or home that is individually its own. From the snail carrying her habitation upon her back to the fowls of the air; from the mole and rabbits burrowing under the earth to the larger animals seeking their lairs in mountain fastnesses—the creature is led by instinct to find for itself an abiding place and to build or select that shelter which is adapted to the needs of the life to be lived therein.

Only man, the highest form of animal life, has, from age to age, changed the form of his habitation, and it is curious to note, in reviewing the past, the evolution of the home. Progress in every form has pushed us from the rude shelter of tents and boughs, log cabins and huts of mud and wood, to the lofty buildings that to-day tower in the Metropolis and fill many of us with apprehension as we gaze upward, optical illusion leading us to see them apparently swaying in space, threatening death and destruction to all beneath.

It has been left to America to illustrate in domestic architecture, in infinite variety, the uses of wood in house-building. One of the first impressions made upon a foreigner is this multiformity in the wooden construction of the dwelling-houses of America. Nearly every order of architecture has been reproduced in wood, to the bewilderment of men who have studied their profession in countries where stone and brick are universally used in building.

America, if it did not inaugurate, may be said at least to have amply exemplified the wooden age in architecture. Criticism in regard to this prevailing use of wood varies with the nationality of the critic. If he be English or Scotch, he is appalled by the apparent lack of stability. The Frenchman is amused at the ornate nature of the ambitious reproductions in wood of that which he conceives should be built only in stone. Germany is more lenient towards American peculiarities, owing to having long been well versed in the adaptability of wood in architecture, and also owing to the German temperament which is endowed with a commendable degree of toleration and a great spirit of criticism, the result of which is seldom given unsought.

The reign of wood, however, is gradually being superseded, even in the United States, and the Stone Age in architecture is advancing with remarkable celerity. In the not far distant future the new continent may even gratify that most severe critic, Mr. Ruskin, and boast of and luxuriate in its ruins. Should fire, storm or earthquake visit Biltmore to-day, the much-admired result would be obtained, and time, which moulds and softens every outline, would soon produce the imperfect and consequently the picturesque which Mr. Hopkinson Smith declares so necessary to the landscape. "It is only," says he, "when the hand of man smirches the face of nature that we really find the picturesque."

Probably no locality is more famed for its summer or country homes than Berkshire county, Massachusetts, and a few illustrations will show better than the most extended critical comment what study and thought have been expended and what results accomplished. Lenox, Stockbridge, Great Barrington, Williamstown, Pittsfield and Dalton are represented; yet there are so many others that are worthy that one must resort to that very charming and healthful recreation and go a-coaching or a-wheeling through the Berkshires to obtain an adequate idea of its beautiful and charming country homes.

Probably there is no more encouraging sign, in these times of advancement and prosperity, than the desire for information upon and understanding of the arts and sciences, and the study devoted to them. Many people are to-day interested in and labouring for the institutions that help toward better things. In the United States, museums, libraries and galleries are slowly but continually growing, and the advancement is just as surely being developed to the welfare of all. The results of this great movement are seen on all sides, and what is more natural and logical than that those so active and instrumental in creating and in maintaining these beautiful influences should themselves dwell in houses that are examples of cultivation and refinement? When one reads the criticisms on public and commercial and on ecclesiastical designs and results, and recognises their justice and force, the task of writing upon domestic architecture becomes a difficult and hazardous one. For if a home expressing the sentiment, taste and refinement of its inmates be not beyond the intrusion of the critic and scoffer, where may we look for seclusion, freedom and relaxation? The difficulties surrounding the designer of a country house are so numerous and insinuating, and so hard to overcome, that many good things are harmed, and the best intentions diverted through sheer discouragement. A design in harmony with the surroundings, and in some degree adapted to the needs and requirements of the occupants, is submitted to the criticism of friends and relatives "who have had great experience in building," and then the mischief begins to develop. Their suggestions, made in all sincerity and honesty, yet without understanding the

situation or object of the design, frequently destroy the scheme of the architect, and the whole is ruined from his point of view, and the spirit departeth from the house. When the architect receives the degree of confidence and reliance shown the legal or the medical adviser, "then shall his sins be upon him." But so long as "we made the plans ourselves, and only got Mr. Blank to draw them out," then should their sins be upon them. One of the first inquiries made when a client explains his wants is, What style or character of a house do you wish? Colonial is popular and frequently desired, and naturally the question arises, What is Colonial? Is it an effort to repeat from memory and without skilled or professional assistance the continental or Adam Brothers style, as so many examples in the southern States and the old manor-houses of the northern would indicate, or is it the low-hipped and gabled style of New England, so attractive in its simplicity and quiet? And here is an opportunity to say a few words upon this problem of the owner's right to build as seemeth best to him and for his own pleasure and comfort, rather than to satisfy the critic or tourist who chances that way. Whom should the architect and landscape gardener first consider? Whom please? and why? Will someone more enlightened give the answer, and thus relieve the minds of many now labouring under the weight of uncertainty and doubt? Another not unusual experience is that the needs and requirements of a family change frequently and radically, and what was at one time the ideal for comfort, convenience and utility becomes insufficient for the needs of the household. This may lead to disappointment and to criticism; but who may see and provide against such emergencies?

Some difficulties are encountered in Berkshire that are not met with in the southern or coast climates, and, after experience, the architect learns to discard many of the features that are so attractive in less severe regions. The middle south, about the vicinity of Cincinnati and St. Louis and similarly situated cities, for instance, permits of treatment that is entirely unsatisfactory in Berkshire, and still greater liberty may be indulged in the cities of Savannah and Charleston, and locations corresponding to them in environment and climate.

The north-west, on the other hand—Minneapolis and St. Paul being typical examples—is more like Berkshire than any other section in its climatic conditions. The severe cold and the curious and damaging results produced by the formation of ice on the shady portions of the roof while the snow melts on its sunny slopes, have taught house-owners and architects many lessons that are not readily forgotten. Yet who, having lived in Berkshire long enough to enjoy her people and her hospitality, has been quite satisfied to leave it? It seems a country so full of beauty, strength and nobility in her landscape that one wonders how any one can live in it and not be generous, strong and true. Nowhere can be seen so many exponents of different styles of architecture, and some, no doubt, deserve severe architectural criticism. But, thanks to the wondrous hills and forests, every outline softens into an effect that gratifies the eye, even while it may sometimes offend the taste of the witness of truth in art. Truly Berkshire, with her inspiration to elevate the standard of the homes of America, need not be ashamed of the results thus far accomplished, and happy is the man called by his profession to add his conception of truth and beauty to its charm, and happier still he who may own, be it a castle or cottage, a home in Berkshire.

## TESSERÆ.

## Flaxman's Sculpture.

THE most distinguished proof of Flaxman's powers in heroic composition, and the strongest mark of his genius may be discovered in the colossal group of "St. Michael subduing Satan," now in the gallery at Petworth, an attempt as successful as daring in columnar grouping, and which affords an example of the difficulties imposed not only by material, but by the nature of the subject, being overcome without a recourse to adventitious aid, by which the eye or mind might be diverted from the impression proposed, and is strictly within the limits enjoined by sculpture. It is, indeed, a work not less skilful in the arrangement of its composition than great in its conception. The archangel is produced in the spirit of the art itself, his countenance denoting a generous indignation tempered by angelic nature. There is an ardour and energy revolving around him which might be supposed to influence him in the execution of his Divine mission; we want no type or wings, but at once admit his presence. The character of the whole is finely marked, and possesses in the choice and structure of form, and in the unity of expression and action, all the ideal qualities appropriate to the exalted subject. In the personification of Satan he has been not less successful. Half monster and half man, with all the characteristics of mighty stature and Titanic strength, in the malignant subtlety and inflexibility of purpose, in expression, and in the writhing

action of the demon, we see him evidently withheld by the presence of a Divine power, in which he is no longer able to sustain himself. In alto or basso-relievo, Flaxman, since the revival of the art, stood pre-eminent. The illustrations from the Lord's Prayer are fine examples of his talents in the simple and natural, whilst the heroic is powerfully displayed in the unrivalled composition of the shield of Achilles. If examined as compositions by the test of analysis or separation, they will bear the strictest scrutiny; if contemplated for the character each bears to the subject, we would not desire more perfect harmony. If regarded for form, grace and the taste which pervade the whole, we may pronounce it a work worthy to be ranked with the distinguished discoveries at Dodona.

### French Medals.

Next to Italy, France is the most remarkable country for medals. Louis XIV. is celebrated for his encouragement of the fine arts; he founded L'Académie des Inscriptions for the purpose of selecting subjects and making designs for medals to commemorate the great events of his reign. The result of the labours of the Academy was the production of nearly 300 medals. The style of art exhibited in these was in accordance with the taste of the period—it wants simplicity. Landscapes and a variety of emblems are crowded together in the backgrounds for the purpose of giving a picturesque effect, which is injurious, the resources of the art being limited in comparison with those of painting. What Flaxman remarks of the limited powers of basso-relievo is particularly applicable to medals, "that a tree or two, some rude stone or a wall slightly marked in the background must indicate a forest, a mountain or a palace without detailing a portrait of their component parts." Napoleon well understood the moral and political influence of the fine arts; his series of 160 medals is an evidence of the care and attention he bestowed upon the Mint, and these imperishable memorials will give immortality to his extraordinary career. They were executed under the direction of Denon. On the obverse of all of them we have the fine profile of Napoleon, and many of the reverses are admirable works of art. The Battle of Jena, Jupiter launching his thunder against the Titans, Mars sheathing his sword after the Battle of Friedland, Napoleon personifying Hercules, with two female figures kneeling and presenting him with the keys of Vienna and Presburg, may be mentioned as examples; but, for the most part, they rather astonish us with a display of mechanical execution. The large medal of the Battle of Marengo is surprising for the minuteness of the workmanship, and the medal of Pope Pius VII., in the coronation of Napoleon, is also remarkable for the execution of the building of Notre-Dame on the reverse. Andrieu, Galle, Droz and Brenet were some of the most celebrated artists employed. But the Napoleon medals are not always implicitly to be relied on by the historian. For example, Bonaparte caused a medal to be struck as a memorial of his invasion of this country. On the obverse, as usual, is the head of the Emperor, and the reverse represents Hercules strangling a marine monster. Around is the legend "Descente en Angleterre," and in the exergue "Frappée à Londres." Happily for us this was struck in anticipation only, and was not issued from our Mint. The medal was afterwards destroyed; some few specimens, however, were rescued.

### An Egyptian Feast.

It was a custom of the Egyptians during or, according to Herodotus, after their repasts to introduce a wooden image of Osiris, from 1½ to 3 feet in height, in the form of a human mummy standing erect, as Plutarch informs us, in a case or lying on a bier, and to show it to each of the guests, warning him of his mortality and of the transitory nature of human pleasures. He was reminded that some day he would be like that figure, that men ought "to love one another and avoid those evils which tend to make them consider life too long, when in reality it is too short," and while enjoying the blessings of this world to bear in mind that their existence was precarious, and that death, which all ought to be prepared to meet, must eventually close their earthly career. Perverted by the Greeks, this warning of the temporary pilgrimage of man served as an inducement to enjoy the pleasures of life while in this world, as if death closed the scene and no prospect was held out of a future existence, a notion directly at variance with the maxims of the Egyptians and the constant mindfulness they were exhorted to cherish of a hereafter, and we find that the Greeks advocated the principle "Live while you may" with unblushing earnestness. The beauties of poetry were summoned to assist in its recommendation, and every lover of excess welcomed and adopted it with sentiments evincing the same spirit as the exhortation of Trimalchio, which is thus given by Petronius:—"To us, who were drinking and admiring the splendour of the entertainment, a silver model of a man was brought by a servant so contrived that its joints and movable vertebrae could be bent in any direction. After it had been produced

upon the table two or three times, and had been made by means of springs to assume different attitudes, Trimalchio exclaimed, 'Alas, unhappy lot, how truly man is naught! similar to this shall we all be when death has carried us away; therefore, while we are allowed to live, let us live well.' The same sentiments were used by the Jews in the time of Solomon." The intent, however, of this custom with the Egyptians was widely different, and even if from long habit and the increase of luxurious manners the good warning it was intended to convey was disregarded or failed in its effect, still the original intention was good and cannot in justice be condemned as tending to immorality; and though Herodotus, who merely says that the guests were requested to "observe that man whom they would all resemble after death," and were exhorted "to drink and enjoy themselves," omits to inform us if it intended to convey a moral lesson, Plutarch expressly asserts this and removes all doubt respecting the object they had in view. The idea of death among the ancients was less revolting than among Europeans and others at the present day, and so little did the Egyptians object to have it brought before them that they even introduced the mummy of a deceased relative at their parties and placed it at the table as one of the guests, a fact which is recorded by Lucian in his "Essay on Grief," and of which he declares himself to have been an eye-witness. After dinner, music and singing were resumed, men and women performed feats of agility, swinging each other round by the hand or throwing up and catching the ball, and the numerous tricks of jugglers, both in the house and out of doors, were introduced to amuse the company.

### Mediæval Vaulting.

Very few Greek or Roman architects have carried technical ability and a strictly correct calculation of the proportions between strength and burthen beyond the master masons by whom churches in the fourteenth century were built. The vaults of several of the larger dimensions are only from 9 to 10 inches thick, and the outer walls, though more than 50 feet high, do not exceed 2 feet in thickness at their summit. The equally clustered pillar, with a comparatively low and sharp arch, prevailed in the first part of the reign of Edward III., over which was placed an open arcade as originally introduced into the Norman churches, and was adopted, as far as the idea only, from them. Of the beauties which characterise the style of this era in particular, a complete specimen offers itself in the octagonal louvre at Ely, which, and the chapel of our Lady attached to the cathedral, were the sole design of Alan de Walsingham, and executed by himself between the years 1322 and 1349. It is certain that architecture was understood and encouraged by ecclesiastics in that age, and it is pleasing to rescue the name of a single practical architect, so eminently superior to others of his own time. Whilst those who designed and completed the great churches on the Continent are recorded scrupulously respecting their talents and works, our own, not greatly inferior to them, are rarely to be ascertained.

### Robert Burns's Experiment in Building.

The poet undertook, for a sum not exceeding 300*l.*, to build a complete farm onstead at Ellisland, on the south side of the Nith, some six miles above Dumfries, consisting of a dwelling-house, barn, byre, stable and sheds, and to permit the proprietor to plant with forest trees the scaur or precipitous bank along the side of the Nith, and a belt of ground towards Friars-Carse, of not more than two acres, in order to shelter the farm from the sweep of the north-west wind. The poet was now a busy and a happy man. He had houses to build and grounds to enclose; that he might be near both he sought shelter in a low smoky hovel on the skirts of his farm. There he was to be found by all who had curiosity or taste, with a table, books and drawings before him; sometimes writing letters about the land and the people among whom he had dropped like a slung stone; sometimes giving audience to workmen who were busy dyking or digging foundations; and not unfrequently brushing up, as Mrs. Burns said, an old song for Johnson's Musical Museum. The walls of the poet's onstead began now to be visible from the north side of the Nith, and the rising structures were visited by all who were desirous of seeing how he wished to house himself. The plans were simple; the barn seemed too small for the extent of the farm, and the house for the accommodation of a large family. It contained an ample kitchen which was to serve for dining-room, a room to hold two beds, a closet to hold one, and a garret, coom-ceiled, to contain others for the female servants. One of the windows looked down the holms, another opened on the river, and the house stood so nigh the lofty bank that its afternoon shadow fell across the stream upon the opposite fields. The garden was a little way from the house, a pretty footpath led southward along the riverside, another ran northward, affording fine views of the Nith and of the groves of Friars-Carse and Dalswinton; while half-way down the steep declivity a fine, clear, cool spring supplied water to the household. The situation was picturesque, and at the same time convenient for the purposes

of the farm. During the progress of the work Burns was often to be found walking among the men, urging them on, and eyeing with an anxious look the tedious process of uniting lime and stone. On laying the foundation he took off his hat and asked a blessing on the home which was to shelter his household gods. On being asked whether Burns did not put forth his hand and help them in the progress of the work, one of the workmen said:—"Ay, that he did mony a time. If he saw us like to be beat wi' a big stane he would cry, 'Bide a wee!' and come rinnin'. We soon found out when he put to his hand—he beat a' I ever met for a dour lift." When the walls rose as high as the window-heads he sent a note into Dumfries ordering wood for the interior lintels. Twenty carpenters flocked round the messenger, all eager to look at the poet's handwriting. In such touches the country is well expressed.

### WANTAGE CHURCH.

**A**BOUT twenty of the members of the Oxford Archaeological Society paid a visit to Wantage on the 25th ult. They were met at the parish church by the vicar, who explained that Wantage parish church dated from the thirteenth century and was probably designed a cruciform church without aisles, the aisles having been added later. The earliest part was the tower, and next oldest portion was probably the chantry on the north side. He called attention to the beautiful fifteenth-century roof of the nave and also to the several old brasses in the church, the oldest being to "Master William Ledding," once vicar of the parish. The tomb of Sir Wm. FitzWarine in the chancel was very old and interesting. The church was restored by Mr. Street and reopened in 1857, and sixteen years ago the church was enlarged by the addition of one bay. The chapel on the south side was restored, decorated and reopened in 1895 as a memorial to the late Dean of Lincoln, who was for thirty-four years vicar of the parish. The architect was Mr. Bodley.

Mr. James Parker, in giving a short history of the church, said it was exactly twenty-five years ago that the Society visited Wantage, when he had the honour of giving them a short address. Having alluded to Wantage as the birthplace of King Alfred, who was born in 849, and who devised several pieces of land in and near Wantage to his wife, he said he thought it probable that the great ruler did build a small chapel or church, though it was not recorded. In the Domesday Book 1085-86, a church was definitely mentioned at Wantage. At one time another church was standing in the churchyard at Wantage, but how long it existed he did not know. There was an old Norman doorway which, when the building was pulled down, was removed to the present Grammar School, where it still remains. He suggested that the smaller church not being large enough for the inhabitants was probably pulled down in the thirteenth century, and instead of enlarging it they built another. He called attention to the massive pillars of the tower arches. He thought the church was enlarged about the time of Edward I. The church, which was originally cruciform in shape, had aisles added to it, and he pointed out the staircase to the belfry on the south side, which was probably built on the outside. The moulding being of different dates showed that the enlargement was not all done at the same time. The work of the fifteenth century was to add the clerestory windows, which would give a better light to the church. The chancel had been considerably enlarged, the character being now rather nineteenth-century although it was originally fifteenth. There was some interesting work of the fifteenth century in the north chapel. The tomb in the chancel seemed to be of one date, while the figure on it was of another date, but judging from the armour it probably belonged to Sir Wm. FitzWarine. He mentioned that lords of the manor did not think their estate complete without a proper church, and that was the reason they had so many beautiful churches throughout the land.

The party then took a walk around the interior and exterior of the church, inspecting the various points of interest, which were described by Mr. Parker.

Afterwards they drove to Childrey and Sparsholt, visiting each church, and then to the ancient "Blowing Stone" familiar to the readers of "Tom Brown's School Days." White Horse Hill was next ascended, and the ancient Roman camp known as Uffington Castle was inspected and a magnificent view obtained from the hill. Several of the party walked a mile further along the Ridgeway to "Wayland Smith's Cave," a well-known cromlech, and mentioned in Sir Water Scott's "Kenilworth."

Uffington Church was next visited, and the octagonal embattled tower and many points of interest in the church were examined.

**The Conservatoire** in Paris, or at least the part to which the public is admitted, will have to be rebuilt at the close of the present year, owing to its dangerous condition.

### The Association Sketch Book.

**SIR,**—In your notice of the second volume of the third series of the Architectural Association Sketch Book I think you do the editors an injustice. I plead guilty to the oversight of inserting Mr. Andrew Oliver's name amongst the contributors as the author, but we cannot claim to be so entirely innocent as you would make us believe. The Sketch Book does not publish any text with the illustrations, and the information has to be condensed within very small limits.

The original pencil drawings, which were very much rubbed, were given us without any information as to what they represented. All the owner knew about them was that they were bought at a sale. It is possible they may be the original drawings prepared by M. Jules Goury, and they certainly appeared like it, but there was no evidence forthcoming that they were so, and therefore the name could not be inserted. Jones and Goury's description of how the ground for the paintings was prepared was added as being of interest, but as I could not obtain positive information as to the subjects intended to be represented I was unable to give it, and to have inserted the whole of Jones and Goury's description would have been impossible without a sheet of letterpress, and to make it complete Marmol's remarks should have been added as to the centre panel being portraits of the ten successors of Mohammed II., who added to the buildings. In the fifteenth century the room was called the Hall of the Portraits (El Cuarto de los Retratos).

Although the Sketch Book was originally composed entirely of sketches by members of the Association, the committee do not see why they should confine themselves exclusively to members of the A. A. either for subscribers or contributors, and any suitable and interesting drawings are accepted. I do not understand on what grounds your review states these plates have no right to be included; certainly decoration is a subject which should receive the attention of one who may any day be called upon to design anything from drains and iron girders to faience and goldsmiths' work.—Yours faithfully,

May 31, 1897.

WILLIAM G. B. LEWIS.

### GENERAL.

**The Salon Exhibition**—the last to be held in the Palais de l'Industrie—will be closed on the 10th inst.

**The Debate** on the reports relating to the Works Department of the London County Council on Tuesday was not brought to a conclusion, and the further consideration of the subject will be resumed on the 28th inst.

**The Foundation-stone** of the new buildings of the Royal Ophthalmic Hospital was laid on Friday last by the Prince of Wales. The building is expected to cost 100,000*l.* The joint architects, Mr. K. D. Young and Mr. Bedells, and the builder, Mr. Grover, were presented to the Prince.

**The French Government** propose to purchase for 421,000 francs the collection of Greek coins of the late M. Waddington. Ten centuries—from the seventh century B.C. to the third century A.D.—nearly all the cities of Asia Minor, and many dynasties and satrapies are represented in this valuable collection, the result of the labours of half a century.

**Mr. Story** has nearly completed the bust of the late Lord Randolph Churchill which is to be placed on the main staircase of the House of Commons, as well as the statue which is to be placed in the chapel of Blenheim Palace.

**The City Council of Toronto** have declined at present to accept the offer made on behalf of various art societies of a scheme of mural decorations for the new city buildings. Artists, selected by the societies as competent to design and execute work of the character, had, at the expense of a great deal of thought and effort, elaborated a scheme of decoration which was intended to be illustrative of the history of the city and province.

**The Royal Institute of Architects of Ireland** have made arrangements with the Royal Institute of British Architects to exhibit during the present week the following prize drawings at the School of Art Galleries, Kildare Street, viz. Royal Institute of British Architects' Silver Medal, the Soane Medallion, the Pugin Studentship, the Owen Jones Studentship, the Aldwinckle Studentship, the Grissell Medal.

**The Royal Archaeological Institute** will hold its annual meeting this year at Dorchester in the beginning of August. Dr. Cox has accepted the position of president of the Architectural Section, and proposes to take as the subject of his address, "The Treatment of the Cathedral Churches of England during the Victorian Age."

# The Architect.

## THE WEEK.

A DECISION which was given in one of the Paris courts on Saturday last will cause some commotion among French artists. Hitherto it was the custom for frame-makers to consider the painters who ordered frames for portraits as agents. Payment was accordingly sought from the people who were represented on canvas. There was no liability incurred by the artists. The public apparently recognised the custom also. But a lady recently declined to pay 450 francs for framing a portrait of herself by M. WEISS. The frame-maker, regardless of precedent, applied to the artist for the money, and when he refused to settle the account an action was brought. The Tribunal would appear to be indifferent to custom which is not supported by documentary evidence, and a decision was given in favour of the frame-maker.

THE peculiar dislike of children which animated SWIFT is one of the weaknesses to which he confesses. He could not pardon Mrs. MASHAM for attending her children instead of intriguing for the benefit of SWIFT and his friends. He was therefore not likely to allow a little child to be placed on his knee, although the boy was to be the great-grandfather of an Irish M.P. But belief is very strong in Ireland, and we wonder Mr. J. G. SWIFT MACNEILL does not make a claim on behalf of a more remote ancestor who might have sat at Marino on the knee of King BRIAN BOROHME before he slaughtered the Danes. So long as belief is allowed to have supremacy we need not wonder at the archæological freaks which are common in Ireland and by which "The Old Tree House" suddenly is changed into Dean SWIFT's old house. "The Old Tree," it is well to remember, was no more than a lofty mark to indicate a cabin which served as a public house. There are many "castles" in Ireland that have a similar architectural appearance.

It is pardonable for the people of Dublin to associate the name of JONATHAN SWIFT with houses which probably he never entered. The Dean, although compelled against his inclination to live among Dublin citizens, never posed as a native. SWIFT's life abounds in mysteries, but his connection with Dublin is the most mysterious of all. He was born, some say, at No. 7 Hoey's Court, a very poor place. Sir WALTER SCOTT says of the house:—"The antiquity of its appearance seems to indicate the truth of the tradition." If every house that looks old in Dublin could be assumed to be SWIFT's birthplace, his biographies would be more puzzling than they are. The latest attempt is to exalt a house in a different part of the city—Lower Dorset Street—as if it were the residence of the Dean. SWIFT had a big official residence adjoining his cathedral; why should so penurious a man keep an additional house so far away that he could not reach it on foot in less than an hour? Mr. J. G. SWIFT MACNEILL, M.P., claims that the house was the town residence of the SWIFTS, of Swift's Heath, County Kildare, that is, of the Dean's family, and that they also held another house known as Marino. He next says:—"Mr. GODWIN SWIFT, a great-grandfather of mine, was fond of relating that when a very little boy he was brought by his father, the Mr. SWIFT of Swift's Heath of the day, into a drawing-room and placed on a gentleman's knee, and that his father asked him always to remember that he had been on the knee of a great man. He believed that the 'great man' was Dean SWIFT, and that the drawing-room was a drawing-room at Marino."

THE efforts which are made to levy exactions on railway companies by municipalities, public companies and individuals are generally amazing. After arrangements are made to satisfy legal claims there is generally some new

necessity discovered at the last moment which is declared to be the most important of all. The North-Eastern Railway Company are having a sad experience of the sort. We have already alluded to the endeavour which was made by the Humber Conservancy Commission to have most costly works carried out in the river as if they were made indispensable by the proposed docks. The Commission so far succeeded that the committee of the House of Commons proposed the introduction of a clause to the effect that if any remedial works are required in the river within a period of ten years after the completion of the docks, "The Humber Conservancy Commissioners may themselves cause the work to be done and restore the said river to its former condition, and may recover from the company the expense to which they may have been put by such dredging and restoration." A meeting of the directors of the North-Eastern Railway was held a few days ago, at which the following resolution was adopted:—"Resolved that, in view of the very changeable character of the river Humber and the alterations that are evidently going on in the channels, as proved by recent investigations, and having regard to the fact that the proposed works, when completed, are calculated to improve and not to injure the river, the directors cannot undertake any liability with regard to the future condition of the river, except as to the removal during the construction or the completion of the works of any deposit in the vicinity of the proposed river walls or embankments, or affecting the entrance to the Alexandra Dock, which may have been caused by the works of the company during the construction thereof; resolved also that the solicitor be instructed, in the event of the clause which the committee may insert in the pursuance of their intimation, imposing any greater liability than the above, to withdraw the portion of the Bill relating to the Hull Dock Works."

THE International Congress on Technical Education will be held at the rooms of the Society of Arts and the room of the London School of Economics from Tuesday to Friday next. Among the papers to be read will be the following:—"Technical Education in Architecture and the Building Trade," by Mr. W. R. LETHABY; "Technical Education in Relation to Lithography and Engraving," by Mr. R. W. BAXTER; "Technical Education in Connection with Process Engraving and Allied Industries," by Mr. W. BOUTALL; "Technical Education in Connection with the Gold and Silver Trades," by Mr. W. AUGUSTUS STEWARD; "Technical Education in Relation to the Manufacture of Glass," by Mr. H. J. POWELL.

THE directors of the Leeds Steel Works invited the members and practising associates of the Northern Architectural Association to visit their works on June 9, to view the manufacture of steel in its various processes, from the ore to the finished girder. A large party of architects accepted the invitation. The members of the Association travelled by the train leaving Newcastle at 10 A.M. *via* Sunderland and Stockton. The Leeds Steel Works received its present title and was registered as a limited company in 1888, but previously was known as the Airedale Iron and Steel Works. Mr. WALTER SCOTT, of Newcastle-on-Tyne, has purchased from time to time the property of the other partners, and he may now be practically termed owner of the works. The company have agents in all the principal cities of the kingdom, and forward goods throughout Great Britain, to the British Colonies, South America, India, Egypt, &c. Mr. W. S. VAUGHAN, of Newcastle, is one of the directors of the company. The works cover an area of 25 acres, the yearly output is 70,000 tons of steel, and the wage roll 70,000*l.* per annum. The stocking ground is commanded by a 10-ton travelling crane, which has a span of nearly 100 feet. The sheds and yards are intersected by railway lines, on which six locomotive engines and eight steam travelling cranes are continuously at work. The electric light is in full use throughout the night.

## THE ANCIENT CHOIR.

THE important letter of the Bishop of CHESTER is likely to revive the controversy about the most eligible position in an English church for the choir and organ. In the majority of cases, owing to the desire for visual effect as well as from a belief that an ancient practice is conserved, the chancel is employed to accommodate them, but it does not always follow that the singing is thereby as impressive as is desirable. We are told that "where there is a chancel arch, central lantern, or transepts, the sound becomes intercepted instead of passing into the body of the church; moreover, where the chancel is narrow, antiphonal singing cannot produce its proper effects." It is also said "that when the placing of the choir in the chancel has involved the removal of the organ also, it has usually resulted in cramping the organ within some confined space or 'chamber,' by which the tone has been damaged and its beautiful qualities and real efficiency impaired." Musicians who consider the successful display of their art as having more importance than either the picturesque or ritualistic needs, consider that the organ should be set up at the west end of a church and the choir arranged in galleries north and south of the nave or outside the chancel screen or in chancel aisles. If the choir must have places in the chancel, then the use of a chancel arch, which is an impediment to the transmission of sound, is to be avoided. Sir WALTER PARRATT, the organist, would have the organ erected in the west end and the choir disposed halfway up the nave on each side. He considers it would be preferable for musical purposes to employ the Greek cross plan in churches, and Sir JOHN STAINER was of the same opinion. Sir WALTER adds that "music is not the only thing which would gain by a fundamental change in our ideas of 'propriety' and 'respectability' in church plans." These are mysterious words, which we confess we are unable to understand, and we suppose most people who read them will probably prefer to be guided by Sir WALTER PARRATT when he confines himself to arrangements which relate to music.

If, as is said, "in many churches congregational singing is ruined by the present arrangement," for the support and controlling power of the choir are too remote to be of any help to the congregation, there may be a change. But it will probably be claimed that there are also a great many churches where the dignity of the chancel has the first place in the thoughts of clergy and people, and in those cases the present system will not be abandoned without regret. The desire which appears to be growing for chancels veiled by close screens, which would be an obstacle to sound as well as sight, may not be without influence in the case. Whatever is decided, all lovers of architecture are bound to hope that no sacrifice of chancel arches in old churches, erection of minstrel galleries or other works of transformation will be recommended. Music is worthy of all respect, but it will be hardly fair to sacrifice architecture to satisfy requirements which after all may not be enduring.

There is a close connection between ritual and building, for a church was planned to suit ceremonial offices. When revolutionary changes are proposed it is therefore advisable to consider what was the most ancient practice relating to the subject which is involved. We may then ask, Was the choir of a church always placed in the chancel? The answer would be in the affirmative so long as "chancel" was not supposed to signify the space immediately around the altar, and which in many places was generally the eastern end of a church. Apparently chancel is only the English form of the Latin *cancellus*, a screen, railing or other construction by means of which an enclosure can be formed; but that screen in the early churches did not subserve the same purposes as those which sometimes separated the sanctuary or presbyterium from the nave, and which are now being revived. The modern chancel screen divides the church from the part which, in a legal sense, does not belong to it; for while the parishioners are charged with the repair of the church, there is no responsibility on them for any neglect of the chancel. The ancient *cancellus* was a barrier only 3 or 4 feet high, which kept a congregation from intruding on the *chorus cantantium*, and a survival of it is still to be found occasionally on the Continent. The late J. H. PARKER writing on the subject said:—

In the south-west of France, as I have myself seen, and as I am informed in Spain also, the chorus (or choir) are usually

placed in the middle of the church, with as much space at the east end as at the west, and the congregation assemble on all sides of the choir, a large proportion being placed between the east end of the choir and the altar. The choir is railed off on all sides, and the altar has a separate railing in front of it. This custom is common in those provinces which were formerly English—Aquitaine and Gascony—and may probably have been introduced from thence into England. It is certain that in many churches in England the choir extended into the nave and was not confined to the eastern division of the building; it was surrounded by a screen separating it from the nave and aisles, and in some instances there seem evident marks of there having been a screen at the east end also. The choir extended only as far as the stalls, the space eastward of the choir being called the presbytery.

If the members of the choir were in English churches placed amidst the congregation, the arrangement would be therefore warranted by precedents, both native and foreign. At Quimperlé, in Brittany, according to PARKER, the choir is raised on a platform in the centre, and compared with it both the nave and the apse for the altar appear "comparatively small and insignificant." Some local custom must have dictated so prominent a position, and the associations have to be strong which can preserve an arrangement which is contrary to the usual practice in the country churches of France. The late ARTHUR ASHPITEL, the architect, found modern practice in Italy to be in favour of movable choirs, and there is much to be said in approval of them, for in a hot country the same spot in a building is not always equally favourable to the devotion of people who have to be close together, and moreover organs can be removed on wheels from place to place. One of his stories is worth repeating:—

I remember an instance where a friend who stood in the eastern limb of a large cross church alluded to it as the choir. "Oh! no, sir," said the sacristan, "this is not the choir, this is the tribune." "Where, then, is the choir?" asked the perplexed stranger. "Why, sir," said the sacristan, "at present it is in the third chapel on your right, but next week it will be in the chapel in the cloisters." At Santa Maria Novella at Florence, it was sometimes behind the high altar, and sometimes in the chapter-house or chapel *degli Spagnuoli*, in the Green Cloisters; at St. John Lateran, before the alterations, the *coro* was before the high altar, now in summer it is behind it, and in winter in a chapel leading out of the transept built for the purpose. At Santa Maria Maggiore the *coro* in summer is in the Sforza Chapel (a side chapel), in winter in a chapel to the right as you enter. At St. Peter's it is generally in the Clementine (also a side chapel) in winter, or in the sacristy. In fact, there is scarcely a church of any size that does not have its *coro d'estate* and *coro d'inverno*—its summer and winter choir.

The choirs serve a double purpose; they are used for the prescribed daily offices for the clergy, when no layman is allowed to be present, and for services in which clergy and laity join. Mr. ASHPITEL gives the following account of the practice in the Clementine Chapel:—

In general the breviary services are sung in the Clementine Chapel—a noble chapel on the left of the nave as you go up. This is filled with stalls and other seats, and has two organs facing each other. At one corner is a small private door leading to the sacristy, through which I was kindly permitted to pass when I pleased, except at the time when the choir was assembled, when a nod from the nearest priest, and the whisper of the word "*coro*," of course sent me back directly. We will suppose the tierce, *tertia*, or nine o'clock morning service, is over, the priests gone, and the metal gates open. It is an ordinary week-day, or *feria*. A little after ten the professional singers assemble, and take their seats in a species of orchestra. The people assemble and fill the chapel, and high mass is performed. When this is over the chapel remains accessible to everybody till noon, when the priests again assemble; the gates are closed, and the *sexta* are sung; and so on of the other services. On Sundays and festivals of higher character, instead of the high masses being sung in this chapel, they are invariably performed in the upper limb of the church, which we would call the choir, and which they call the tribune, the laity filling that portion of the building, and coming as near the altar as convenience will permit: a very great proportion of the high altars abroad have no rails. But on the great *funzioni*, or highest festivals, when the Pope himself says mass, it is at the altar under the dome, the great concourse of the laity filling the nave. In fact, I believe through the Continent the various portions of the church are used, *mutatis mutandis*, according to the number of people expected to attend, and in the best way convenience may dictate.

In great churches, like St. Peter's or Santa Maria in Florence, it is possible to have itinerant services, and the

choirmen follow the priest. But in ordinary village churches so many changes are not possible. In English churches "fixity of tenure" for the choir will also be declared as requisite. But, as we have said, the foreign examples suggest that a choir can have a place temporarily or permanently among a congregation, without any diminution of their efficiency as aids to the service of the day or their dignity as representatives of any special order of men.

How did the choir as a part of the Christian Church originate, and was any special office distinct from ordinary laymen assigned to those who formed the *chorus cantantium*? FERGUSSON says the introduction of the choir attached to the bema or presbytery was the last great change in development of the basilica into a church. He tells us how "round three sides of the choir the faithful were allowed to congregate, to hear the Gospels or Epistles read from the two pulpits or *ambones* which were built into its enclosure, one on either side, or to hear the services which were read or sung by the inferior clergy who occupied its precincts; the enclosure of the choir was kept low, so as not to hide the view of the raised presbytery, or to prevent the congregation from witnessing the more sacred mysteries of the faith which were there performed by the higher order of clergy." But FERGUSSON does not attempt to explain why the introduction of a choir was a necessary stage in the evolution of a Christian church, or why it should be assigned a place that was evidently abstracted from the naos or nave which belonged to the laity. The accompanying plan of

PLINY records that the Christians declared their only fault was in meeting before sunrise on certain occasions to sing hymns to CHRIST as to a god ("carmenque Christo quasi deo dicere secum invicem"). The whole night seems to have been occupied with psalms, lessons and prayers. The singing was most simple. In Egypt and Syria the custom was apparently more faithfully preserved than elsewhere, and several of the early hymns originated in the churches there. Men and women (*monazantes* and *parthene*) appear to have devoted themselves to vigils and singing. They formed guilds and confraternities, which were non-official. In the fourth century they were allowed admission to churches in Antioch in early mornings and in the evenings before and after the regular services. The Eastern custom extended to Italian cities, and through a part of Gaul. In fact, the institution of periodical watching was familiar in various cities of the Empire before it was introduced in Rome. The early services, which commenced at cock-crow, and those at night, were not presided over by the bishop, and were less formal than the ceremonies at which all members were bound to assist. What was more natural than to hold them in a part of the church which, while special to the society, was separate from the *presbyterium*, which the clergy were alone privileged to possess? Women as well as men could attend, and in consequence some irregularities followed. On that account VIGILANTIUS demanded the suppression of the services at night, and St. JEROME recommended one of his correspondents to

San Clemente, Rome, shows the position of the most perfect example of the ancient choir which has survived. The arrangement dates at least from the beginning of the fifth century. In some Mediæval Spanish churches we can also see choirs which encroach on the nave, and most disadvantageously to the general effect, for instead of a *cancellus* of 4 feet in height there are high walls which spoil the perspective view.

As the choir was not a part of the church from the beginning, and as it is not found in a vast number of buildings, we can only conclude it was not originally, nor is it now, an essential part of a church. There may be devotional services without singing or music. It is true that in Rome chanting had become so perfect an art that when BENEDICT BISCOP visited the city in the seventh century he solicited, besides a plan for his new monastery at Wearmouth, that one of the singers should be sent with him in order to train his monks to sing anthems and responses in a style that seemed to be derived from celestial choirs. But some centuries were needed to bring chanting to that state, and the Christians of the first or second century would be likely to be as much surprised as the Englishman at the harmony which had been attained. We might say that the choir was absent from primitive churches because the Roman authorities did not value music. Like so much which is accepted as characteristic of the Roman Church, the necessity was created for it and the supply furnished from without. Apparently the earliest occupants of the choir were the representatives of the faithful who, on the vigil of Easter, kept watch. Afterwards every Sabbath eve was celebrated in a similar way.

prevent her daughter from attending them without a guardian. Afterwards, on the creation of monastic orders, the *coro* became their part of the church, and the early confraternities were superseded. Mr. ASHPHTEL, who gave much attention to the subject, says:—

After the sixth or seventh century, a new rule or order was springing up—a body separated from the secular clergy grew into existence, and exercised the most important influence in all ecclesiastical matters. The Eremites, or dwellers in the wilderness of Egypt, under the rule of Antony or Pachomius, now extended themselves gradually over the whole Christian world in the form of various monastic bodies, and with their increase grew up new constitutions, new customs, the most important of which, and one that seems wholly to have been overlooked in this investigation, is the establishment of a custom among all bodies, where a "conventus" or assemblage of clergy could be found, that another entirely separate set of services distinct from those of the laity should be daily observed. The time at which their observation first began is very uncertain. The great Roman authority Carranza places it in that of Pope Damasus I. (371), but our learned Bingham and Joseph Meade consider it to have grown by degrees, and not to have been perfected till many years later. A service specially used by the monks in the morning and evening is noticed as early as the time of Cassian; but the regular observance of those called the canonical hours, or the breviary services sung by the monks at every third hour of the day and night, seems to have grown up so gradually it is impossible to fix its date. But at the same time with this change sprang up the difference in the choir of the churches, which difference in the building no doubt sprang from the rising idea that there were services peculiar to the clergy from which the laity ought to be excluded. The best authority probably is that of Durandus, who tells us that "in the Primitive Church the peribolus, or wall which encircles

the choir, was only raised elbow-high, and which is still observed in some churches, whence it came that the people seeing the choral clergy might thence take a good example. But in *this* time (he goes on to say) almost always a veil is hung up or a wall interposed between the clergy and the people, lest they should mutually look at each other."

What is said by DURANDUS about his own time will explain the cause of the seclusion of the Spanish choirs. As they were appropriated to the clergy alone, it was considered fitting there should be isolation. The monks were better organised than the members of the laity, whose pathetic psalm-singing, after the manner of Antioch, brought abundant tears from the passionate emperor THEODOSIUS, for instead of allowing themselves to be scattered among the general congregation, like the earlier occupants of the choir, the monks established churches of their own, where they could spend long hours at night as well as by day in repeating the strange melodies in which the spirit of Asia and Africa were expressed along with that of Europe. The proposal therefore to bring English choirs away from the neighbourhood of the altar and to settle them amidst the congregation is only a return to ancient ways, and we trust that if architectural alterations are needed, inspiration for them will be drawn from the low rails of San Clemente rather than from the Spanish enclosures.

## METHODS OF CHARGING FOR ELECTRICITY.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

IN considering the value of any commodity the question of supply and demand has to be taken into consideration in arriving at the true value of the article, and this principle is one which should be carried into every department of trade.

The best example of the effect of supply and demand affecting the price of services rendered or of a commodity is perhaps that of a seaside hotel. The cost of accommodation in the "season" is, so many people think, excessive, but it is not so when consideration is given to the fact that sufficient money has to be obtained in the two or three months' season to keep the proprietor and his family, pay the rent, rates and taxes, and the other incidental expenses for the whole year. If people would only patronise his house uniformly all the year round, several economies could be enforced. (1) A smaller house would suffice for the same turnover, and smaller rent, &c., also fewer servants. (2) A far greater number of people would share the expense between them, and so each would be charged less, and the cost of living would be quite moderate. This simple case is given fully, as it corresponds almost exactly with that of the supply of electricity to consumers. The important point which they have in common is that no storage is possible in either case. The number of rooms in a hotel must be proportional to the greatest number of visitors, and the amount of plant in an electricity supply station must be proportional to the largest number of lamps turned on at one time, no cheap form of storage having been invented in either case.

With the supply of gas and water the case is very different. Gasholders and water reservoirs are cheap compared with the value of the gas or water they store, but electric accumulators are not. In the former cases a small plant can work continuously, the inequalities in the demand being supplied from the storage. It follows that the only extra expense entailed in these cases is that of the larger mains and of the storage, both of which are small when compared with the expense of the large plant required to supply the maximum demand without storage, and the bad economy caused by irregular working. For these reasons water can be sold by the 1,000 gallons and gas by the 1,000 cubic feet, without reference to the time of day or the regularity of the demand, with approximately equal justice to the company and all consumers.

With electricity supply the matter is an entirely different one, and, as before mentioned, the case of the seaside hotel is a very useful illustration. The visitor in the season in the one case is the consumer who in the other has his lights on for the time of heavy load only, in fact, when almost everyone else has lights on, and as a consequence he should be charged extra. The consumer who uses light

in the daytime is like the winter visitor, who is charged very little, in fact, only just more than enough to cover the extra expense entailed.

This now shows us the justification for a charging system which charges a price proportional to the cost of supplying the particular units sold.

This inequality in the cost of supplying electrical energy was early recognised by HOPKINSON and KAPP, the former of whom worked out the cost and proved that the cost of supplying electricity cannot be correctly defined at so much per unit, unless the rate of supplying that unit be also stated, and further that the cost depends more upon the greatest rate at which the units are generated than on the number of units. As a result of his investigations he urged that the price charged should bear some comparison to the cost of supplying at the time it is demanded.

A system was arranged by Dr. HOPKINSON for Manchester to carry out the result of the above investigation, partially at any rate. The system is as follows. A charge of 1s. 4½d. (nearly) is made per quarter for every 8 candle-power lamp (30 watt) connected, and all the electricity used is charged at 1½d. per unit. The effect of this is obviously that the consumer who uses a few units per lamp connected per annum pays a high price per unit, and the one who uses his lamps a long time pays a very low price. This system, however, is not all that could be desired, as a consumer might have many lamps wired, but never have them all on at one time. He thus has to pay for more than he has demanded. This objection was removed in other towns by the invention of Mr. WRIGHT (electrical engineer to the Brighton Corporation) of the demand indicator. This demand indicator is a maximum thermometer which shows the greatest current that has been demanded since it was last examined.

At Hastings the Manchester system has been adopted, but instead of the charge being so much per lamp connected it is:—A charge of 1s. per 8 candle-power lamp *on at one time* per quarter is made, and the electricity is charged at 3d. per unit. (The maximum number of lamps on at one time being registered by a demand indicator, mentioned above.) The higher charge for current is to bring the revenue up to about 8d. per unit sold, whereas in Manchester it is 6d. per unit sold.

The system introduced by Mr. WRIGHT at Brighton is the one which has attracted the greatest attention of any, and as a result it has been the one most criticised. The system is based upon the analysis of the accounts of the station, which show that there is a loss on those consumers who have used their maximum demand for less average time than one and a half hours per day, the selling price being 7d. per unit, the actual running costs, *i.e.* the cost of generating extra units, being 8d. only, the rest 6½d. per unit being the standing charges such as interest on capital and the expense of keeping the station in readiness to supply the maximum demand. The WRIGHT system consists in charging 7d. per unit for the first hour and 1½d. per unit afterwards.

There are, then, three systems, all the outcome of the work of Dr. HOPKINSON, and all embodying two principles, viz. that the cost of supplying electricity depends upon the greatest rate at which the units are demanded, and that the price charged should bear some comparison with the cost of supplying at the time of demand.

As this paper is not written from the central station point of view, but that of the consumer, the analysis of central station costs will be as brief as possible, and will merely show that the principle is just.

The central station about which we have most information for this purpose is at Brighton, and this is a very flourishing station of large size, thus everything is in favour of the consumer. The following particulars are taken from Mr. WRIGHT's pamphlet relating to his system of charging.

Mr. WRIGHT, for the purpose of his analysis, states that the cost of supplying electricity is the revenue required to make the station self-supporting. He finds that a comparison of monthly and quarterly statements of total expenses shows how slightly these vary, and how much the receipts vary. He divided the expenses into "running" and "stand-by" charges. Running expenses include properly, coal, oil, water, engine stores and repairs caused by continued supply.

Stand-by costs:—All coal and oil to get up steam and in keeping boilers ready to supply the engines, in keeping the mains ready to supply electricity; all stores used in station, on mains; all wages debited to revenue account; repairs to mains and meters, buildings, and repairs to plant due to its being kept ready for work, rates and taxes, management expenses, insurance and all provisions for redemption of capital and interest on capital, and for creation of a depreciation and reserve fund. The only items not easily divided in the proper proportions are coal, stores and repairs. Mr. WRIGHT finds for the first two (coal and stores) that the average cost per unit is the difference of the total expenditures under these two heads in two periods divided by the difference of the two sales (in units); the two periods should be ones in which very different amounts of energy are supplied. The remaining point, repairs, can be best settled by dividing the total cost of this item since the station started by the number of units supplied, and this is the running cost under this head per unit.

Mr. J. W. GREENE in America has pointed out that the standing charges should be divided into three parts:—

1. Preliminary expenses,
2. Connection costs,
3. The costs proportional to the maximum load,

and Mr. Wright has found that the chief factor in determining the monthly expenditure in central stations is the maximum annual load the station must meet, and that after the first year or two it will be directly proportional to this load.

At Brighton the costs under these headings are:—

- |                  |                   |
|------------------|-------------------|
| 1. 6.3 per cent. | } 83.3 per cent., |
| 2. 11     "      |                   |
| 3. 66     "      |                   |

and running costs 16.3 per cent.

Mr. WRIGHT has found that the sum of these three expenses is proportional to the maximum annual demand. No. 1 or the pioneer expenses go on continuously owing to extensions of mains and machinery, those laid down being in excess of those required to cope with anticipated increase, thus the expense decreases per kilowatt; No. 2, or connection expenses, increase per kilowatt, as the large consumers become exhausted and the cost of a connection is the same for a small as a large one. No. 3 is by definition proportional. The decrease in No. 1 makes up for the increase in No. 2.

It has thus been shown on the authority of Mr. WRIGHT that the cost of supplying electricity can be divided into two parts:—(a) Standing; (b) running; that the stand-by charges are in a representative station proportional to the maximum annual demand, and that by definition the running expenses are those proportional to the units sold.

The ratio of (a) to (b) at Brighton is  $\frac{83.3}{16.3}$ .

Now, on these results, a theoretical system would be to charge a fixed sum per annum for each consumer proportional to his share of the demand on the day of maximum load, and a small price to cover the running costs and to give a little profit, say, 1½d. per unit, for all electricity supplied.

From the consumer's point of view, the Manchester system does not approach this, because whether a consumer uses his lamps in the day or night, winter or summer, or never uses all his lamps at once at any time, he has to pay his share proportional to the number of lamps he has, and not to the number of lamps he uses at one time. The Hastings system is the best of the three systems as regards the approach to the theoretical, as the latter objection, viz. that the consumer may not have used all his lamps at any time, yet is charged as if he had, is removed. The other objections remain.

The Brighton system is in many respects far from perfect. The consumer pays the full price until he has paid off his share (based on his maximum demand) of the standing charges, and he then has the rest of his supply at a reduced rate (1½d. per unit); thus the very bad consumer does not pay any more per unit than the one who just uses enough current to pay his share of the standing charges, and, in fact, the loss (before mentioned) on those consumers who use less than the least paying quantity for their maximum demand has to be paid by charging a price far

higher to those who do (1½d. per unit when the running costs are 8d. per unit only). For this reason the Hastings system is a better one, and more just, than the Brighton.

None of these three systems take into account the time at which the current is used, but charge proportionally to the number of lamps or the maximum demand only, and to the quantity of electricity used; in fact, the price is less as the consumer's load factor (the ratio of the actual consumption to the consumption if the maximum number of lights had been used for the whole time, day and night) is better.

(To be concluded.)

## THE POSITION OF CHOIR AND ORGAN IN CHURCHES.

IN a letter to the editor of the *Times* the Bishop of Chester writes:—The Upper House of the Convocation of York recently requested the President to appoint a committee to inquire into and report on the considerations which should determine the position of organs in churches. Since then, as mover of the resolution, it has been my privilege to receive proofs of the interest taken in the matter by organists and choirmasters of the highest authority, and, as the work of a committee is aided by public attention, I would ask leave to bring the subject before your readers. It obviously has interest not only for musicians but for architects and church building committees, for diocesan chancellors—who are constantly being asked to grant faculties for the removal of organs—and for the lovers of vocal and instrumental music through all denominations.

As is well known, the dominant fashion—"a perfect mania," "a fashionable folly," are terms used by two of my correspondents with regard to it—is to place organ and choir at the east end, even in small district churches, and to do this as a matter of course with little or no discrimination, forgetting that—to quote Sir John Stainer—"it is most difficult to lay down any general law as to the proper position of organs in churches, because so much must depend upon (a) the shape and ground plan of the church, (b) its size, (c) its acoustical properties, and (d) the character of its services."

That both the importance and the manysidedness of the question have been already recognised will be seen if I can be permitted to quote rather copiously from a valuable document, for the use of which I am indebted to Sir Walter Parratt's kindness. Some years ago he served on a committee, jointly nominated by the Royal Institute of British Architects and by the College of Organists, to consider musical requirements and arrangements in churches. Unfortunately, their report did not reach the final stage, and was therefore lost to the public; but I learn that there was substantial agreement upon the principles and recommendations contained in the draft report, from which the following extracts are taken. I cannot but think that, if this draft could be placed at the disposal of the York committee, their work would be much more than half done, and done under particularly advantageous conditions:—

After a careful review of the arrangements which are now usually made for the accommodation of the choir and organ, the committee desire to record the following observations:—

- (a) That the arrangements are generally defective.
- (b) That there is much misconception as to the best positions for the choir and organ in their relation to each other and the congregation.
- (c) That the space allowed for the modern organ is often insufficient.
- (d) That on musical grounds the old position at the west end for both organ and choir is, in general, the best.
- (e) That although for ritual purposes (following the ancient English cathedral and collegiate arrangements) a vested choir is placed in the chancel, yet that where there is a chancel arch, central lantern or transepts the sound becomes intercepted instead of passing into the body of the church; moreover, where the chancel is narrow, antiphonal singing cannot produce its proper effects.

(f) That when the placing of the choir in the chancel (according to recent custom) has involved the removal of the organ also, it has usually resulted in cramping the organ within some confined space or "chamber," by which the tone has been damaged, and its beautiful qualities and real efficiency impaired.

(g) That the arrangement alluded to above is not the most advantageous for the support and encouragement of congregational singing.

(h) That these defects are more or less the result of adapting new customs and requirements to old buildings, and are not always to be avoided.

(i) That, as a result of the general improvement in knowledge and taste, the increased facilities for the musical render-

ing of the services, and the more frequent bringing together of large bodies of singers and instrumentalists, the provision of better accommodation for them is a problem which must be considered.

#### *As to New Churches.*

The main object of this committee is to promote the improvement and development of the arrangements of new churches, and they have taken as their basis the musical requirements of a large town church; these requirements would necessarily be modified for small town or country churches.

There would appear to be but five positions in which the choir can be conveniently placed in a church:—

1. At the west end of the nave.

It is commonly admitted by musicians that the most effective position for the organ is at the west end; but this position is not always advisable if the choir be retained in the chancel.

2. In galleries facing each other in the nave.

The advantages claimed for seating the choir in galleries (similar to the ancient "minstrel galleries") on the north and south sides of the nave are as follows:—(a) The better support of congregational singing; and (b) the opportunities afforded for antiphonal effects. (All "galleries" are subject to special conditions.)

3. Immediately outside the chancel screen.

4. In the chancel aisles.

5. In the chancel.

With regard to these latter positions, it is advisable, in planning a new building, in order to obtain the openness and space requisite for the sound to reach all parts of the building, that a "chancel arch" should be avoided, and the choir thus placed under the same roof as the congregation. This will enable the clergy as well as the choir to be properly heard.

In churches exceeding 150 feet in internal length the plan of placing the main choir at the west end, and a "ritual choir" in the chancel, may be adopted.

#### *As to Existing Modern and Ancient Churches.*

In dealing with existing churches, whether ancient or modern, the principles set forth in the "Recommendations" should, as far as possible, be observed; but each case should be individually considered. In those places (for example) where there remain a western organ and gallery of interest, at a distance of not more than 50 feet from the choir seats in the chancel, it is desirable that each should be retained *in situ* and used; and where the distance is more than 50 feet a small additional eastern organ to support the choir is recommended.

#### *Recommendations.*

No. 8.—That the term "organ place" be adopted, because it is more comprehensive (including gallery, &c.), and because the term "organ chamber" is misleading, inasmuch as a chamber (or enclosed place) has been determined to be not suitable for an organ.

No. 13.—That the organ should never be placed between the choir and congregation.

No. 14.—That the sound of the organ should not have to pass over one-half of the choir to reach the other.

No. 15.—That when possible the organ should be equidistant from both halves of the choir.

No. 16.—That the choir be placed on raised floors or in low projecting galleries architecturally treated.

That Sir Walter Parratt is still of the same mind is shown in recent letters from which I am allowed to quote. Thus, he writes:—"Personally, I favour the west-end position for the organ, and I should place the choir halfway up the nave on each side. Many churches have narrow chancels from which neither organ nor voices can be heard, and the congregation finds itself without encouragement to sing and without support and control if it makes the attempt. I am, of course, well aware that considerations of space and ritual make the removal of the choir difficult and even distasteful to many people. But I am convinced that in many churches congregational singing is ruined by the present arrangement." It is noteworthy that both Sir John Stainer and Sir Walter Parratt look forward to a time when architects will be less conservative, and have the courage to adopt more suitable arrangements for musical purposes. They both think that "the experience of our modern wants shows the superiority of the Greek cross as a ground plan." Sir John remarks that "music is not the only thing which would gain by a fundamental change in our ideas of 'propriety' and 'respectability' in church plans."

I wish I could give extracts from other weighty and independent opinions, all much to the same effect. But I have already overtaxed your space, and the distinguished authorities whose testimony I have cited will be ample evidence that, in the interest of public worship, the matter calls urgently for attention.

The '91 Art Club will hold their annual exhibition of members' works at Clifford's Gallery, 21 Haymarket, during the latter part of the month.

#### ANCIENT EGYPTIAN GLASS.

THE skill of the Egyptians in the manufacture of glass and in the modes of staining it of various hues was so successful that they counterfeited with success the amethyst and other precious stones, and even arrived at an excellence which their successors were unable to retain, and which our European workmen, in spite of their improvements in other branches of this manufacture, are still unable to imitate; for not only do the colours of some Egyptian opaque glass offer the most varied devices on the exterior, distributed with the regularity of a studied design, but the same hue and the same device pass in right lines directly through the substance; so that in whatever part it is broken, or wherever a section may chance to be made of it, the same appearance, the same colours and the same device present themselves, without being found ever to deviate from the direction of a straight line, from the external surface to the interior. This quality of glass has been already noticed by the learned Winckelmann, who is decidedly of opinion that "the ancients carried the art of glass-making to a higher degree of perfection than ourselves, though it may appear a paradox to those who have not seen their works in this material." He describes two pieces of glass found at Rome a few years before he wrote which were of the quality above mentioned. "One of them," he says, "though not quite an inch in length and a third of an inch in breadth, exhibits, on a dark and variegated ground, a bird resembling a duck, in very bright and varied colours, rather in the manner of a Chinese painting than a copy of nature. The outlines are bold and decided, the colours beautiful and pure, and the effect very pleasing, in consequence of the artist having alternately introduced an opaque and a transparent glass. The most delicate pencil of a miniature painter could not have traced with greater sharpness the circle of the eyeball or the plumage of the neck and wings, at which part this specimen has been broken. But the most surprising thing is that the reverse exhibits the same bird, in which it is impossible to discover any difference in the smallest details; whence it may be concluded that the figure of the bird continues through its entire thickness. The picture has a granular appearance on both sides, and seems to have been formed of single pieces, like mosaic work, united with so much skill that the most powerful magnifying glass is unable to discover their junction. From the condition of this fragment it was at first difficult to form any idea of the process employed in its manufacture; and we should have remained entirely ignorant of it had not the fracture shown that filaments of the same colours as on the surface of the glass and throughout its whole diameter passed from one side to the other, whence it has been concluded that the picture was composed of different cylinders of coloured glass, which being subjected to a proper degree of heat, united by (partial) fusion. I cannot suppose they would have taken so much trouble and have been contented to make a picture only the sixth of an inch thick, while by employing longer filaments they might have produced one many inches in thickness, without occupying any additional time in the process; it is therefore probable this was cut from a larger or thicker piece, and the number of the pictures taken from the same depended on the length of the filaments and the consequent thickness of the original mass. The other specimen, also broken, and about the size of the preceding one, is made in the same manner. It exhibits ornaments of a green, yellow and white colour on a blue ground, which consist in volutes, strings of beads and flowers, ending in pyramidal points. All the details are perfectly distinct and unconfused, and yet so very minute that the keenest eye is unable to follow the delicate lines in which the volutes terminate; the ornaments, however, are all continued without interruption through the entire thickness of the piece. Sometimes, when the specimens were very thin, they applied and cemented them to a small slab of stone of their own size, which served as a support at the back, and by this means they were enabled to cut them much thinner, and consequently to increase their number.

#### THE ROYAL INFIRMARY, GLASGOW.

A CORRESPONDENT of the *Glasgow Herald* writes:—In regard to the proposal to remodel the front or other parts of the Royal Infirmary in commemoration of the Jubilee, no plan has yet been placed before the public. It may, therefore, be of some interest, and may even stimulate the flow of contributions to a laudable object, if we present, in however bare outline, a definite scheme, and consider the whole question in relation to its physical surroundings. The medical aspect of the case has been discussed at some length, although the proverbial difference has yet to be adjusted; but it is by one of the faculty that the first public recognition has been made of an architectural standpoint as regards the square, which, though it be not utilitarian, should not be overlooked. At the risk of exposing another profession to the charge of widely divergent opinions, we desire to take this architectural view, and first with regard to the infirmary itself.

Hospital planning is pure science. No question of artistic beauty or architectural tradition can be permitted to influence the disposition of the building to the detriment of its great purpose. Like other departments of science, it has no finality, because new methods of ventilation, of heating, of lighting, may entirely upset the bases of all arrangements or calculations hitherto. For such reasons the resolution passed at the doctors' meeting, that no more beds be put upon the site, is empirical, and unworthy of a body of scientific men. It is part of the purpose of this article to show that a much larger number of beds may be put upon the ground in the most economical way, while the salubrity of the site would be enhanced instead of impaired. It goes almost without saying that if any part of the infirmary be radically reconstructed a revolution must be wrought in its principles of lighting and heating and ventilation, and this may affect its whole design. To adopt any other system than the "plenum," or some modification thereof, would be a gross error in the situation occupied by the building. Apart from questions of graveyard emanations, and without entering into the question scientifically, the casual observer cannot fail to be conscious of the volumes of smoke which, especially in north or east winds, drift past the infirmary. In the plenum system, already employed in the Victoria Infirmary here, the air is introduced by mechanical appliances, and however smoke-laden or otherwise impure is artificially cleaned, and warmed if necessary, and then driven through the wards. It may also be treated antiseptically and disease germs killed as the foul air is drawn off, so that they cannot do damage in other wards. Windows are thus rendered entirely useless for purposes of ventilation, and the construction of separate and widely sundered pavilions of several storeys becomes an extravagant and a cumbersome method of arrangement. Instead, therefore, of super-imposed wards, lighted on both sides by windows, let the wards adjoin on one level, well raised above the ground and packed underneath, and be lighted from the roof by large glazed lanterns or dome lights, which would catch the sun when it shines at any hour of the day. By this method the wards are massed together on one level and the service rendered economical and immediate; while they are thoroughly warmed and effectively ventilated by the system already described. In this way we return to models like the "Ospedale del Ceppo," at Pistoja, of the sixteenth century, which, without mechanical ventilation, yet does good work. No question of cheerfulness of outlook from windows can enter into the matter, for the prospect in any direction (except to the square), and especially over the adjacent burial-ground to the farther Necropolis, can scarcely claim a salutary or enlivening influence on a hospital patient. All that can be said in favour of the site is that it is open, elevated and central, and it is these advantages precisely which make it suitable for an experiment that has not yet been attempted on a large scale, but which is unquestionably in the direct line of the utilitarian evolution of hospital planning. One-storey wards would accommodate a number nearly equal to half the present accommodation of the whole buildings. By the removal of the present surgical block to the east the whole space would be rendered available for these new medical wards, and the surgical cases displaced might occupy the existing front building. This would also improve the salubrity of the whole hospital, but is not essential to the plan, for the present eastern block might remain, and be disused only on its ground floor for wards. The administration buildings might be built of two storeys, and from the upper level might be made to afford from a gallery a bird's-eye view of the whole of the beds in the wards.

As to the front range of buildings under sentence of destruction, the position of those who care for our street architecture, and for our civic history in so far as it is written in stone, may be said to be:—Here is a dignified, unpretentious and scholarly, if not brilliant production, a work which tells its own tale, and is representative of an original phase of Renaissance due to the initiative of Robert Adam—a building carefully studied in its relation to the cathedral, and in full and quiet harmony therewith, though presenting the greatest possible contrast of style. If possible, it should be spared. Under any circumstances we are not likely to have a building of anything like equal dignity. If of one storey its restricted height, if of several floors the necessity for ample lighting will be sufficient of themselves to make the modern substitute a meaner thing. Of course, by great good fortune the man of the moment might turn up who, out of these unpromising materials, might create a joy for ever and a never-failing adornment of the cathedral square. But safety, as well as economy, lies in the conservative course, especially as the building, if ill adapted even for the surgical wards of an infirmary according to modern ideas, is not with certain alterations impossible as a medical school or out-patients' department, &c. And whether the front is destroyed or rebuilt in its present shape, one thing should be resolved upon, that the reconstructed building shall not advance one inch beyond its present line. Its alignment with the cathedral, though not exactly parallel, is perfect in its artistic effect; and if change is

to be made, the front should rather be set back, so that the north side of the cathedral be better displayed.

The cathedral of St. Mungo is rarely seen by visitors in its exterior aspect. The statement may need some qualification, but as a matter of fact few visitors do more than walk from the gate to the south porch which admits to the interior, and as they must return this way they rarely do more than cast a backward glance at the building from the highly unfortunate line of this approach. Many an English parish church stands up more grandly at its south-west angle than our own cathedral (Selby and St. Mary Redcliffe, for example), and yet few even of the English cathedrals have much greater nobility and power than our cathedral viewed from the south, the north-east, or any point on the Necropolis. This is, of course, due largely to the nature of the site in its downward slope from its west end. That our too hurried visitors may carry away some worthy impression of the exterior of the cathedral, the authorities should in the first place negotiate for an entrance off the Necropolis Road, opposite the south porch and alongside the superintendent's house. The present entrance has the advantage of being tolerably direct both from Mason Street and High Street, and, although not the most obvious, is not difficult to find. But the one proposed would be more direct to foot passengers from High Street, much more direct from John Knox Street (the best approach), and nearly as direct from Mason Street.

It would be interesting to know what percentage of visitors take the trouble to walk round the very confined precinct to view the cathedral on the north, or stray into the dismal burial-ground. To see the cathedral properly it is necessary to leave the precinct and go round to the corner of James Orr Street and Wishart Street, a long detour. What is wanted is a street, approached from Mason Street or High Street, affording easy communication with Wishart Street, and permitting of a ramble round the cathedral. It would encroach on the burial-ground, but it might be turned into a public *campo santo*, and might even be reserved for privileged persons with monuments of corresponding importance designed and executed with taste. Few existing monuments would be interfered with save that they might have to be turned round, and the part of the proposed street to the north side appears yet to be unappropriated. In this way the ground would not be alienated from its purpose, while a picturesque foreground would be formed to the north-east aspect of the cathedral. After half-past four at this time of year the sun shines full on this north side, for the cathedral points considerably to the north of east. In a simple, natural and inexpensive way we should then revive the beautiful Greek and Roman custom of the public street of tombs, which with the Greeks, as at Assos and Athens, was placed just without the western gates of the city, whither the citizens walked at sundown. An entrance to the Necropolis at the foot of James Orr Street would enable one to make a most interesting journey round the cathedral, taking in the Necropolis without too much expenditure of time or energy. The Institute of Architects are bestirring themselves to secure that visitors should see the interior of the crypt, and have invoked the aid of electricity to replace the natural light, of which the lower church has been deprived by its stained-glass windows. The idea is a bright one, and it is to be hoped that the Board of Works will see it in that light, and in conjunction with other public bodies interested will do what in it lies for the proper display both of the exterior and interior of the grandest architectural monument in Scotland.

#### EDINBURGH ARCHITECTURAL ASSOCIATION:

THE Association on Saturday last visited, by permission of the Rev. John M. Johnstone, Torphichen Church, the chief centre of the Knights of St. John in Scotland. Mr. Henry F. Kerr, who conducted the party, explained, in the course of his remarks, that the Hospital of the Knights was probably founded in 1153, when the order was introduced into Scotland. An old archway occupying a site under the westmost arch of the crossing was probably the chancel arch of the first church. The rest of the Mediæval remains were of late pointed work, consisting of north and south transepts, with at the crossing a tower, which must originally have been a bold feature with its cope house gathered with crow steps. The vaulting of the transepts and crossing was still standing, but in some places the vaulting-ribs were badly split and some of the vaulting-stones had fallen out. On the motion of Mr. Thomas Ross a vote of thanks was given to Mr. Kerr and the Rev. Mr. Johnstone.

Lord Kelvin will preside at a dinner on the 14th inst. which is to be given by members of the Whitehall Club to Mr. F. H. Webb, the retiring secretary of the Institution of Electrical Engineers.

## NOTES AND COMMENTS.

It is not easy to satisfy all classes of people in Paris. They expect much from the International Exhibition of 1900, but they will not make any sacrifice in order to facilitate the preparations. There must, for example, be Salon exhibitions and exhibitions of the rival societies in 1898 and 1899, although at present there is no building at the disposal of the Government or the Municipality in which so many paintings can be shown. The painters and sculptors would be losers by any suspension of the annual exhibitions, but the visitors would make more of an outcry. While it is agreed that in the summer of next year and of the following year Paris cannot be deprived of its exhibitions, the problem of discovering a spot where the temporary shelter can be set up is still unsolved. The garden of the Palais-Royal, which seemed a suitable site, has found more opponents than was anticipated. The Place du Carrousel, or rather the garden between the statue of GAMBETTA and the Pavillon Sully, is now under discussion, but objections against it arise on all sides. If the Government erected the buildings there might be less difficulty in approving of that site, but as the work will mainly be carried out by private enterprise it is anticipated that the speculators will not be over-scrupulous in their endeavours to recoup themselves for the large outlay. The Société des Artistes Françaises will contribute 12,000*l.* But that sum will only meet one-half the cost of the temporary buildings. The remainder of the money has been offered on the condition that the buildings can be used for exhibitions, fêtes and other enterprises during the ten months of the year which remain after the Salon closes. To have a sort of fair during several months in so important a part of Paris is almost enough to make the ghosts of the former tenants of the Louvre and the Tuileries arise against the degradation. The risk of fire is also to be considered. If the flames extended to the collections of the Louvre, it would be little consolation to know that the wooden buildings were erected to save Parisians from the inconvenience which might arise from the absence of a Salon during a few weeks. It is, of course, declared that, owing to the precautions, any likelihood of a conflagration may be set aside, but, considering how primitive are the means for coping with fires in Paris, the authorities before agreeing to the proposals will do well to insist on a temporary organisation being arranged, which shall have as much efficiency as is considered necessary by English experts. As to the Champ de Mars, a salon there would be a failure.

A FEW years ago a correspondent of *The Architect*, in describing the late M. ALPHAND, the director of municipal works in Paris, said of him:—"If the offices which are so efficiently held by Sir J. W. BAZALGETTE, Mr. VULLIAMY and Colonel HAYWOOD in London could be combined they would be far from corresponding with that of the Directeur des Travaux de Paris. What is done in London by Government bodies and public companies is as much under the control of M. ALPHAND as work like that of the engineering and architectural departments of the Corporation and the Metropolitan Board of Works. M. ALPHAND is also responsible for the supply of water to the city, for the condition of the Seine, for the survey of Paris, for the decoration of the public places, for upholding the amenity of the most beautiful of capitals. He has one department where constant observations are being made by a staff of chemists and meteorologists on the air and water of Paris, and where the movements of bacteria are watched as closely as those of the criminal classes by the Préfecture de Police, while in another department folio volumes are being prepared on the history and topography of old Paris." On M. ALPHAND's death it was felt that another man was not to be got readily who would be competent to grapple with such multifarious duties. Accordingly there was a new arrangement of the offices. But it was soon discovered that administration did not become more effective, and a return to the old system was advocated. But where was the chief to be found? The Municipal Council have considered the question, and their choice is at last one of their own officials, M. BOUVARD. He was one of M. ALPHAND's trusted assistants, and he succeeded to the most important of the divisions of the master's empire. His conduct during the visit of the rulers of Russia won him golden opinions from the Government

and the Municipal Council. M. BOUVARD did all that was required, and allowed the elected of the people to take the credit. Such a suppression of self deserved a reward, and it has been given. That, in addition to the ordinary duties of the office, the new directeur-général will have the supreme control of the works of the International Exhibition, need hardly be noted. Extra responsibility involving some millions of pounds is only a bagatelle to a man who has to bear extraordinary loads every day.

THE Court of Assistants of the Drapers' Company have passed a resolution to the effect that Mr. T. G. JACKSON, R.A., be requested to advise them as to the erection of a building suitable for the Radcliffe Library, Oxford, on the site which it is understood is available for it, and should it be found that such a building could be erected for the sum of 15,000*l.*, the Company will be happy to undertake the erection of it, of course in the first place submitting the architect's plans to the University authorities for approval. The existing library is too small, and in consequence much inconvenience is caused to members of the University and other scholars who desire to consult the books. On the 15th inst. the following decree will be proposed:—"That the cordial thanks of the University be returned to the Worshipful Company of Drapers for their munificence."

JEAN TIJOU was apparently one of the Frenchmen who were induced by Sir CHRISTOPHER WREN to emigrate to England. WALPOLE describes him as a "founder of iron balustrades," and he was employed at Hampton Court and St. Paul's. His "New Booke of Drawings" appeared in 1693, and a copy is now very expensive. It contains twenty plates. The style which they represent was in much favour in France, and the most remarkable examples of it are to be found in Nancy, which were produced by JEAN LAMOUR for King STANISLAUS. Strange to say, the screens and balconies look better in masses as there seen than single examples such as are found in England. The old principles of construction, which were revered by the Mediæval smiths, were not of much account to JEAN TIJOU or JEAN LAMOUR. Both were eager to display large leaves and other forms of vegetation in gold. They never wished to suggest that the ornament was a part of the construction, but rather that the gilded pieces were blown on the curved or contorted bars, or were attracted by them. In modern times we have made a nearer approach to Mediæval examples, and, however ornate, JEAN TIJOU's pieces are not much appreciated. But they will always be curious, as evidence of what was supposed to be dignified in art in the early part of the last century, as a record of the extravagance in form which was imposed on this country in spite of the national good sense. Mr. BATSFORD's reproduction of TIJOU's book will serve as well as the original, and is obtainable for a fraction of the price which is paid for the Dutch engravings.

## NORWICH CATHEDRAL.—V.

THE vaulting which is to be seen in Norwich Cathedral is not of the finest type, and does not display much acquaintance with geometry by the designers, or skill in stone-cutting by the masons. More excellent work is to be found within the cloisters, of which part we show an illustration. The vaulting of the cloister was studied by Professor Willis, and his conclusions were as follows:—

The cloister is the work of successive periods, but the intention of the successive architects was evidently to make their continuations assimilate with the beginning, in which they have so well succeeded that at the first glance the entire work appears to be of one design.

This expression of uniformity is principally due to the employment of single simple shafts with base and capital in lieu of mullions throughout the tracery, for the pattern of the latter varies and assumes in turn the peculiar fashions, Geometrical, Flowing and Perpendicular, that belong to the age in which each was erected. But the external arch which contains the tracery is of the same figure throughout.

I am informed by one of the canons residentiary, who has taken much pains in the investigation of matters relating to the structure of the cathedral, that the outer wall of the cloister is Norman, so that in all probability an early cloister (perhaps of wood) existed previously to the present one upon the same site, and was replaced piece by piece by the latter as funds or convenience permitted.

The vaulting throughout is of the same plan, namely, each severy is nearly a square, there are transverse, diagonal and wall ribs (the latter term also including the rib which lies next to the tracery) and one tierceron between each. The ridge ribs are horizontal. The curvature of the ribs, however, is different in the different periods, and it is to the variations in this respect that I wish, in the present article, to direct attention.

The oldest vaults are the central severies of the east walk, with which, according to W. de Worcestre, the work was commenced in 1297. The south walk appears to be the next, and the whole of its vaults have the same character, but differ from the former. The west walk, which is also uniform in character, is the next in order; and the middle compartments of the north walk are, like the tracery which accompanies them, of decidedly Perpendicular style, and correspond to the period (1430) at which, the same author tells us, the cloister was completed. With respect to the extreme compartments of the east and west walks, the character is far less decided. The account given by W. de Worcestre contains a history of the work, with the names of those who carried it on; but there are some difficulties in the application of these particulars, and he has only furnished the dates of the beginning and end of the work, as above quoted. I am inclined to think, from remaining appearances, that the vaults were in some parts left unfinished for a long time after the walls were completed, and that only the *tas de charge* was built, as we commonly find it even now in other buildings, for the curvatures of the ribs at the springing show traces of having been changed to accommodate the new fashions which had arisen when the ribs and vaults were added. For our present purpose, however, I shall select four examples, one out of the middle of each walk, the character of which is decided, and which will stand in order of time thus:—

(1) East, 1297. (2) South. (3) West. (4) North, 1430.

The dimensions and form of the ribs in these four compartments were accurately measured.

The curvatures were obtained in the following manner:—A rod 3 feet in length had a plumb-line suspended from its upper end. The lower end of this rod was placed upon the abacus and close to the springing of the rib whose curvature was to be

measured, as at M. The upper end was brought into contact with the same rib as at *a*, so that *dD* represents the position of the plumb-line. The horizontal distance *MD* (the versine of the arc *Ma*) was then measured, and thus the position of the point *d* of the arch determined. Evidently any number of points in the arch may be determined in the same manner by applying a series of rods of known lengths, as one of 4 feet from *M* to *c*, another of 5 feet from *M* to *b*, and so on. But if the rib consist of a single arc of a circle one such measurement is sufficient, provided the height of the *a* can be measured, which is easily done, especially where the ridges of the vault

are horizontal and the altitudes of all the ribs consequently alike, as in this Norwich cloister. For the height of the wall rib is easily obtained and serves for all. And since the spans of the ribs are all known from the plan, we have thus three points, *M*, *d*, *a*, given in a position for each rib, from which, when laid down to scale upon the drawing-board, the centre and radius of the arc can be found.

This method of measuring the curvatures has many advantages for travelling observations, for it requires merely a ladder to reach the impost and can be carried on without help. Also a slight deviation from the horizontal position of the measuring rod *MD* produces no appreciable error in the result. If on account of the distortion of the rib from settlement, which is always more or less to be expected in Middle Age work, the radius determined by this method should not be very accurate, it at least gives very precisely the middle plan of the spandrel from the very nature of the process. And besides, the point *d* is contained in the *tas de charge*, which being constructed of solid masonry, is not liable to suffer from settlement in a way to alter the curvature of the ribs, whereas any settlement of the shell of the vault changes the form of that portion of the ribs which lie above the solid masonry, so that we can only depend upon the *tas de charge* for giving us the original curvatures. But the spreading of the walls and piers by throwing the *tas de charge* out of the perpendicular will, of course, affect the accuracy of the versine *MD*. To get rid of this source of error I measured these versines at every one of the four corners of the severy in each of the examples and took the mean of the four that belonged to each rib. For the most part, however, I found but little difference. However, for accurate results, observations should also be made with rods of 2 and 4 feet. A rod greater than 5 feet cannot be managed in this way without assistance. Care must be taken that the plumb-line be suspended from that corner of the rod which is placed in contact with the rib.

The following table contains the spans of the wall and transverse arches, and the altitudes of their crowns respectively, also the versines (or distances *MD*) measured as above described and the radius of each rib determined by the drawing-board, upon which the points were laid down to a scale of 1 inch to the foot. The small figures which accompany the radii show the distance of each centre below the impost plane in inches and tenths.

The principal object of this table is to give the form of the middle plan of the spandrel solid, and the accuracy of this result may be relied on. The radii are of course only determined approximately for want of a sufficient number of points in the ribs. One obvious source of error in this case is the assumption that the ridge rib was intended to be horizontal, for as one of the points through which the arc passes is laid down upon the assumption that the height of all the ribs in the severy are alike, it is plain that if this were not the case the error would affect the radius. However, the radii here given will produce vaults having as nearly as possible the same form of the spandrel solid as those from which the measurement was taken, which appears to me to be the most important point. In fact, at present the crowns of the vaults in the eastern walk have sunk about 3 inches, and thus disturbed the horizontality of the ridge; but the form of ridge so produced is so irregular and so different in the different compartments, that it is evidently the result either of bad workmanship or of settlement, and not of design. On the other hand, in the west walk the crowns of the vaults are slightly raised, and this I suppose to be intended to allow for the effect of a similar settlement, for it is not considerable enough to be intended to give a domical form. These circumstances have been duly allowed for in determining the radii. The transverse, tierceron and diagonal arches of the north walk are, however, four-centred, and I was unable for want of time to determine with proper accuracy the radii of their upper circles or the proportion of the two.

Norwich Cloister.	East Walk.	South Walk.	West Walk.	North Walk.

diagonal ribs . . .	9 4 21	8 8 16'5	8 8 15	6 7 0

Fig. 2 shows the form of the middle plans of the spandrels in the four selected examples obtained from the curvature of the ribs. In the east walk, *ADAD* are the diagonal ribs, *AT* the transverse rib, *AWAW* the wall ribs and the intermediate lines the tiercerons. The dots at the extremities

of these lines show the points at which the fillets of the ribs pass through this middle plan, and it will be seen that in this case the points W D W form a rectangle or double square, and that T is on the side of this rectangle; but the tiercerons retire slightly within it. The appearance of this spandrel solid is that of a mass decidedly rectangular in its horizontal sections, but the angles of which are rendered more prominent by the retiring inwards of the tiercerons. In the second plan representing the south walk, no letters of reference are added, as it is in general system exactly like the preceding. In this vault the diagonal, wall and transverse ribs still form a square mass, but the tiercerons advance beyond this mass instead of retiring within it, thus giving an imperfectly polygonal character to the whole, or rather constituting a double polygon with unequal angles.

In the third plan for the west walk, the diagonal rib retires within the rectangular form, and the transverse advances beyond it, so as to give a completely polygonal figure to the mass in its horizontal sections, but yet to make a polygon with unequal angles. This is a very favourite section for vaults of this period. But in the north walk the ribs (with the exception of the wall rib) are semi four-centred arches, having lower circles of the same radius, and consequently the north plan (taken through these lower circles) is an equiangular polygon. But as the curvature of the wall rib is greater than that of the others, its position in this section is thrown nearer to the centre, and this, by causing the vaulting surface to meet the wall at an acute angle, relieves and detaches the entire spandrel from the wall in a very bold and striking manner. The same effect will be observed in the two previous examples south and west.

It thus appears that the form of the middle plan changes by gradual succession from a square to a polygon, and as the three first examples consist of ribs of a single arc, these changes of form are all brought about by varying and altering the radii and the positions of the centres of the respective ribs.

Similar forms to all these may be found in cotemporary vaults, but it rarely happens that they occur in a series and in a work of which the general uniformity of design is manifestly preserved, so that the changes may be regarded in the light of embellishments or as the modern improvements of their day. In this respect the Norwich cloister is exceedingly valuable, by enabling us to discover many of these improvements which it is more difficult to pick out from examples complete in the character of their own age.

A walk round the cloister will at once show, by bringing the various forms into direct comparison, how much influence the form of the spandrel exerts upon the character of the work; and upon considering the various methods by which the different radii and curvatures of ribs in a vault might have been determined, and the probable motives for the different forms they are found to have assumed, I cannot discover any that have a greater appearance of probability than that of giving a certain form to the spandrel solid; for the shape of this, as determined by its horizontal sections, is so obtrusive a characteristic of every vault, and the variations of it appear to succeed each other so regularly, that I cannot suppose them to be accidental. Besides, the motive thus supplied for changing and adjusting the curvatures is of so practical a character and produces such tangible results, that it is much more likely to have been the true one than any occult numerical or geometrical relations between the radii of the several ribs. How easy it is, for example, in looking at any given vault with a view to copy it, to observe that its diagonal rib is too prominent, and therefore requires its centre to be thrown higher up or its curvature increased in order to make its middle points retire inwards, and this is precisely what has happened in the successive compartments of Norwich cloister.

Analogous changes of form constitute in effect the materials for a history of architectural decoration in general. Whatever propriety or beauty a given form may possess, we find that by long-continued use and multiplication it falls upon the eye and requires change. The very characteristic by which it pleased the most, and which was nurtured and developed by every possible adjunct, will be in the next age softened down and subdued to make way for the prominence of some other, which was once in the same manner avoided or made subordinate. So in the series of spandrels we are now considering, the square section at first pleased the eye, and was rendered more prominent by the retirement of the tiercerons; but in the succeeding

specimens this effect is gradually softened down until we obtain an equiangular polygon. But there are also mechanical reasons, as well as those derived from beauty of form, that may account for the growing preference of the polygonal section, for in the latter forms (as also in the fan vaults) the horizontal sections constitute arches that oppose the rising of the haunches of the ribs, and thus the ribs mutually stiffen each other through the intervening surfaces. This is not the case in vaults of a square section, in which the transverse rib receives no such assistance from the diagonal. It would lead me, however, far beyond the proper limits of this paper were I to enter into mechanical considerations, which I have hitherto avoided.

I have said that the spandrel is detached from the wall by so managing the curvatures of the wall rib and first tierceron that the vaulting surface may meet the wall at an acute angle. The beauty and effect of this may be understood by looking at the opposite effect in the vault of the cathedral. This is a lierne vault of elaborate pattern, but of very rough workmanship. The curvature of the ribs is rude and broken, and displays so little management that I am tempted to believe the vault to have been wrought out by country masons with very little or no geometrical knowledge or system. The wall rib, instead of rising upon stilts and retiring, as in most clerestory vaults, for the purpose of making way for the window, is, on the contrary, an arch of a lower crown than the ridge of the vault and is very straight-sided and misshapen in form. The transverse ridge rib rises considerably in the middle, and is curved so as to form a real segmental arch, and the middle plan of the spandrel is nearly a semicircle. The effect of these arrangements is that the spandrel seems to adhere timidly to the wall instead of springing boldly across the space, as in the vaults of the cloister.

#### BRISTOL AND GLOUCESTERSHIRE ARCHÆOLOGICAL SOCIETY.

THE spring meeting of the Bristol and Gloucestershire Archæological Society took place on May 26, when there was an enjoyable trip to Birdlip, Brimpsfield, Elkstone, Cowley and Coberley. The pretty village of Birdlip was visited. In good time the George Inn was reached. The magnificent prospect from various points of the gardens of the inn—slightly spoiled by the prevailing haze—having been viewed by the company, they grouped themselves on the lawn to hear a description of the objects and places in the neighbourhood.

##### *What the Romans did.*

The Rev. W. Bazeley said the road in front of them was a branch of the great Roman road from Glevum to Cirencester, and the piece before them was one of the straightest bits of road in that part of England. The road had been but little altered on the whole. On the left was Crickley Hill, where there existed a camp, the earthworks of which were hidden from their view. He did not know whether it was a British or a Roman camp. Very likely it was British and was utilised by the Romans.

In 1879, the year when the Archæological Society visited that neighbourhood, a very interesting discovery was made. A man was working in a small quarry, when he found a number of stones set on their end, with flat stones on the top. It proved to be a tomb in which were three skeletons, with their feet towards the south. The two outermost were males and the other was a female. The lady had an interesting bronze bowl, beautifully chased, lying on her face and a smaller bronze bowl beside her. A fibula of silver, which had been gilded (very much like a safety pin), was also found, together with some rings of brass and beads, evidently part of a necklace. The necklace showed that she had been married. There was also a beautiful bronze mirror, lacquered on one side and chased with bugle pattern on the other. The remains were removed to the Gloucester Museum, which was closed now, but which, it was hoped, would be reopened later on. The remains belonged to a Roman-British period, probably after the Romans had gone. They were evidently Roman work, which the British learned from their conquerors.

In front of the company was the site of a Roman villa at Witcombe (which the members of the Society visited in 1879), and of the Roman baths and stables, where horses were bred and kept for the purpose of carrying out the Roman travelling and posting system. That system was exceedingly interesting and complete. Within an area of five miles there would probably be three posting stations and 120 horses ready for immediate use. By means such as these a Roman officer might journey 100 miles a day from one end of Britain to another. On the hills around were telegraph stations, where, by a series of signals, messages could be conveyed of the approach of a Roman officer, when horses would be got ready and brought to a given point for his use. As an example of the strength and fineness of the Roman roads, the speaker mentioned that when the Great Western Railway was made, and the road in the neighbourhood was crossed, so hard was it that it had to be

blown up with gunpowder, the workmen being unable to break it up with tools. He explained how the roads were made—of four separate strata—all laid with very great care, and under the supervision of a Roman official. Roads of such substantial and enduring character were necessary for the postal system, and for the rapid transit of troops when emergencies arose.

Mr. H. G. Madan spoke of the derivation of the name Birdlip. He said its true origin was uncertain, but an impression prevailed that it came from the Scandinavian Bythar Lipr, the name of a Viking, passed to butter lip, and thence to Birdlip. Mr. John Bellows was of opinion that the name Ermine Street came from the Cymric A'r Mynd.

#### *Brimpsfield Church.*

While the party partook of lunch rain fell, but happily it cleared off, and the weather was bright for the drive to Brimpsfield, where the party were received in the quaint and interesting church by the Rev. R. Denne (the rector), who gave a short account of the church. He said that, like most of the churches on the Cotswolds, this church had its origin in Norman times. Osbern Giffard made several gifts to the Abbey of St. Stephen at Fontenay, and amongst them was a piece of land at Brimpsfield, on which the monks of the abbey established a priory. Much of this Norman work exists in the church. The south doorway and the chancel arch are of a Norman date, and the nave and chancel stand on their early foundation. The north lancet window and the piscina under the window on the south side of the chancel are in the Early English style, and Perpendicular windows have been inserted on the south side. It is uncertain whether there ever was an east window, or whether it was omitted when the east wall was rebuilt. The tower of sixteenth-century work is placed at the east end of the nave at its junction with the chancel. It stands with its eastern wall partly over the chancel, and the other wall rests on blocks of masonry, which project east and west into the chancel and nave. These have a very singular appearance, and are difficult to understand, but they may be thus explained. The earliest part of the block is without doubt the Norman chancel arch, to which was added in the thirteenth century buttresses and half-piers projecting westward, and on these a bell turret rose, occupying the position of the present tower. It is assumed that this turret became dilapidated and dangerous, and that it was for this or some other cause removed, and then in the sixteenth century the present tower was erected, and to carry this more masonry was built on to the west and east sides of the old chancel arch, of Early English work, all of which can be traced. This masonry, therefore, is a mixture of Norman and Early English work, enclosed and backed up in Perpendicular, and the work of the tower is carried thereon.

The Rev. W. Barclay added some further explanation of the interesting church. It consists of a nave, a chancel and a low inserted tower, with its east wall resting on the original Norman arch of the chancel. It would seem that when the church was built, in the twelfth century, it had no tower, that a small bell-turret was inserted in the thirteenth century, resting on the chancel arch eastwards, and on two columns with circular capitals westwards, and that in the fifteenth century this turret was superseded by a larger tower, with narrow openings and arched buttresses on the north and south, and a plain pointed arch on the west. This tower was also supported by buttresses in the chancel and against the external walls. There is no east window—not an uncommon arrangement in small Gloucestershire churches—but the side walls are pierced by windows, to display the paintings which occupied the space above the high altar. The staircase to the rood-loft remains, of the same date as the tower. The pulpit is constructed of carved oak, with the date 1658. There is a Perpendicular font with delicate panelling. It is thought that Brimpsfield Church was part of a priory or cell belonging to the Benedictine Abbey of St. Stephen, Fontenay, Normandy, which was founded here by the Giffards; but it was probably a parish church from the first. In the churchyard are the remains of three coffin lids with floriated crosses, which no doubt covered the bodies of ecclesiastics. Brimpsfield Priory was confiscated by Henry V., and bestowed on the collegiate church of Windsor by Edward IV. The field on the north of the church is called the Priory Field, and the traces of foundations of buildings are clearly seen there in very dry weather. On the south-west of the church is a large space, surrounded by a deep moat, the site of Brimpsfield Castle, built by the Giffards soon after the Conquest, and demolished by order of Edward II. in 1321, when that sovereign was at Cirencester. In the following year John Giffard, lord of Brimpsfield, was drawn, hanged and quartered at Gloucester for high treason, and his estates were conferred on Hugh Despencer. They were held subsequently by John Maltravers, Maurice de Berkeley, the Earls of March, Katherine, Queen of Henry VIII., and the families of Bridges, Sandys and Pitt. Brimpsfield Park, now the Court farm, is mentioned by William of Worcester as lying along "Le fosse (Ermine Street) ultra Syssetre." On the roof of some cottages to the west of the church may be seen a turret or finial and an ornamental

chimney, which probably belonged to the castle or priory. The site of the castle appears to have been used as a quarry by the people of Brimpsfield for ages.

#### *Brimpsfield and its lords.*

The company passed from the church to the mound on the south side of the church, supposed to be the site of Brimpsfield Castle, where the Rev. W. Barclay gave an interesting account of the structure and those connected with it. The manor of Brimpsfield, which at the time of the survey, 1086, included Cranham, belonged in the time of Edward the Confessor to Duns, a Saxon thane, who held it of Earl Harold, the last Saxon king. It was taxed at nine hides, or about 2,000 acres. It was farmed with fifteen ploughs, three of which were used for the lord's land. There was a parish priest, and therefore also, no doubt, a parish church and two mills on the Frome, in the Cranham valley, yielding 12*l.* to the king. It was held in 1086 by Osbern Giffard, whom Mr. Ellis believes to have been a son of Walter Giffard, lord of Longueville, who fought at Hastings, and was made Earl of Buckingham by the Conqueror. Osbern Giffard also held the manors of Stoke Giffard and Rockhampton, and a hide in Oldbury-on-the-Hill. The Benedictine monks of St. Stephen's Abbey, Fontenay, Normandy, in 1086 held land given to them by him at Middleton, and either he or one of his successors gave them land at Brimpsfield on which they constructed a priory or cell. The parish church became attached to this priory, and also the advowson of the living. The *sobriquet* of "Gifard," which seems to have been given first to Walter de Longueville, meant in old Norman-French a person with fat cheeks and double chin, and hence a cook, because that employment has a tendency to develop such exaggeration of human features. The pedigree of the Brimpsfield Giffards is made very perplexing by the fact that at least four Helias Giffards held the manor in succession. Osbern was dead in 1096, as Helias Giffard I. in that year gave part of his wood, called Buckholt, to St. Peter's Abbey, Gloucester, and William II. confirmed the gift. In 1121 Helyas Giffard, who is believed to be the same Helyas, his wife Ala, and son Helias, gave Buckholt to the same monastery. Helias Giffard II., who married Bertha, sister of Walter de Clifford, and acquired with her great possessions, gave to St. Peter's the church of St. Mary, Boyton, and the church of St. George, Orcheston, in Wilts, and the chapel of St. Andrew, Winterborne, in Dorset. He was present at the chapter-house of St. Peter's Abbey when the Archbishop of York and the Abbot of Gloucester, on December 15, 1157, settled a long-standing dispute between them relating to Standish and other manors. About the year 1165, when his wife Bertha was yet alive, he gave Cranham to the abbey, and entered the monastery as a shorn monk. Helias Giffard III., son of Helias and Bertha, paid a fine on taking possession of the manor in 1165-66. In 1165, with the consent of his mother, he gave Abbot Hammeline eight libræ of land in Ullingswick, Herefordshire, in exchange for Cranham. Later on the monks of St. Peter's gave up all claim to the churches of Orcheston and Winterborne on his confirming their right in Boyton Church. In 1180 he made a grant of wool out of Buckholt to the brethren of St. Sepulchre's Leper Hospital at Gloucester. He died in 1190, leaving his son Thomas or his grandson Helias his heir. His wife was called Maud. In 1201-2 Helias Giffard IV. was a minor in the custody of William, Earl Marshal. He was the son of Thomas and the grandson of Helias Giffard III. In 1210 he was with King John in Ireland. In 1214 the Barons, under Robert FitzWalter, rose in rebellion against John, and compelled him in the following year to sign the Great Charter at Runnymede. Helias sided with the barons, and took up arms with them. In 1216 he and his brother Osbert were excommunicated by the Pope for rebellion against John, and imprisoned. Brimpsfield Castle was seized by the king. In 1216 John died at Newark, and Helias giving his allegiance to the young King Henry III., who was crowned in Gloucester in that year, his lands were restored to him. In 1221 the Abbot of Gloucester complained that Helias Giffard had erected a scaffold, and was hanging his own men at Brimpsfield, to the detriment of the abbot. In 1225-29 Helias confirmed a grant by his brother Osbert to the Hospital of St. Bartholomew, Gloucester, of land called Hullitemed, in Brimpsfield, for the health of his soul and the health of the souls of his three wives—Isabella, Alice and Ysend. About 1230 he granted to his kinsman, Nicholas Caleway, land called Grofruge, in Brimpsfield, and Caleway gave it to St. Bartholomew's. Helias died in 1248-49, leaving his son John his heir. John Giffard, the next lord of Brimpsfield, is described by the chronicler Rishanger as a soldier of great courage and no less integrity. The history of Brimpsfield Castle becomes now very interesting, locally and nationally. It was probably built soon after the Conquest, on the site of a Saxon fortress. It is said to have had a massive central tower and four smaller towers at the angles. All that remains to mark its site is a deep mound with outer banks, surrounding an area of several acres. During the reign of Henry III. the Welsh, under their brave princes, Llewelyn

ap Jorwerth and Llewelyn ap Griffith, made frequent attempts to throw off their allegiance to the British Crown and to regain their liberty. Henry III. made several expeditions into Wales, with varying success. John Giffard took part in these in 1246, 1247 and 1248. In 1261 he was made governor of St. Briavel's Castle, at that time a post of great danger and responsibility on the Welsh marches. In 1263 Simon de Montfort, the great patriot Earl of Leicester, rose at the head of the barons to drive the hated foreigners, who filled well nigh every office, from the realm. John Giffard and the Earl of Gloucester joined De Montfort, and these three became the leading spirits of the movement. Robert of Gloucester, a monk of St. Peter's Abbey, is the principal authority for this period of English history, and his chronicle, from its many references to Gloucester and the neighbourhood, is exceedingly interesting to the local historian. It is evident that he was an eye-witness of the stirring events which he describes as taking place in the years 1263, 1264 and 1265. Henry III. had made a French knight, Sir Maci de Basile, sheriff of Gloucestershire and constable of Gloucester Castle, whilst the barons had given the shrievalty to Sir William Traci, a Gloucestershire knight. On Sir William attempting to hold his court Sir Maci came down upon him with an armed force, dragged him through the mire and imprisoned him in the castle. Whereupon Sir Roger de Clifford and his kinsman, Sir John Giffard, besieged and took Gloucester Castle, and led Sir Maci a prisoner into the Welsh marches. Then Sir John raided Sir Maci's manor of Sherston and drove all the live stock to Brimpsfield Castle. Sir Roger de Clifford, returning to the royal party, gave Gloucester Castle into their hands, and there was constant warfare between Gloucester and Brimpsfield. The Constable of Gloucester held a hundred court at Quedgeley, and summoned Sir John as a rebel before him. Sir John came with an armed force and slew some and dispersed the rest of the Constable's men. In February 1263-64 Sir John Giffard and Sir John de Balun came to the gates of Gloucester riding on woolpacks and covered with Welsh mantles, as if they were merchants, but when they were admitted they threw aside their cloaks, leaped from their horses and stood before the astonished porters armed from head to foot. The porters threw down their keys in alarm and fled, and the knights admitted Sir Simon de Montfort, Sir Henry, his son and many more. So the city was taken, but the castle remained in the hands of the king's party. Then came Prince Edward on Ash Wednesday and assailed the west gate, but was driven back. Turning to the Castle-mead and seeing one of the Abbot's vessels sailing to Tewkesbury, he seized it, and crossed in it to the castle. There were daily contests between the two forces till the Bishop of Worcester and the Abbot of Gloucester mediated between them and obtained a truce. The Barons' party withdrew from Gloucester on condition that Prince Edward should do no injury to the burgesses, but as soon as his foes were gone he broke the truce, imprisoned the principal citizens and hanged the unfortunate porters who admitted Giffard and De Balun. Then soon after was fought the battle of Lewes, in which Sir John Giffard was taken prisoner at the first onset, but the Barons won the day, and the king and the prince were captured. Those who escaped took refuge in Bristol Castle. A quarrel between Sir Simon de Montfort on the one side and the Earl of Gloucester and Sir John Giffard on the other arose concerning the ransom of Richard King of the Romans and other prisoners taken at Lewes, and the latter joined the king's party. After Easter, Sir Simon de Montfort, accompanied by his prisoners Henry III. and Prince Edward, marching to Hereford, remained several days at Gloucester. The Earl of Gloucester encamped in the forest that then extended from Iron Acton to the suburbs of Gloucester, whilst Sir John Giffard kindled a fire on a hill called Erdland, probably High Broadridge, where the single ash tree, like a mighty ship in full sail, now forms such a striking landmark, to assure the prince that friends were nigh at hand if he could effect his escape. From thence Montfort marched to Hereford, and there Prince Edward succeeded in eluding his captors and joining De Clare and Giffard. Gloucester was taken and all the bridges and shipping destroyed, with a view to preventing Montfort crossing the Severn. On April 2, however, he crossed below Worcester, and the battle of Evesham, so fatal to the cause of English liberty, was fought and won by the prince and his supporters. De Montfort was slain, and hundreds of his friends and allies perished with him. The castle of Brimpsfield had been held by way of security for the fidelity of Giffard to the king, but it was now restored to him, and he was pardoned for his rebellion. But Sir John, brave as he was in the tented field, was as yet a bachelor. He was not to remain so long. In 1270 Maud Longespee, widow of the son of the Earl of Salisbury, made complaint to the king that Sir John Giffard had carried her off by force from the manor of Kaneford, and was detaining her at his castle of Brimpsfield. Giffard, nothing daunted, pleaded that the lady was willing, though coy; and the king forgave him on condition that he paid him 300 marks for marrying without royal consent. Maud made the best of the situation, and they lived happily together till her death. Sir John married

twice again—Alice Maltravers, and then, in 1285, Margaret Neville, by whom he had a son, John Giffard, who succeeded him. In 1283 Sir John founded a cell or college at Oxford—Gloucester Hall, now Worcester College—as a residence for the young Benedictine students from Gloucester, Winchcombe, Malmesbury and other abbeys and priories of that order. This, he said, he did for the health of his soul, and for the health of his wife's soul, Maud Longespee. Giffard took an active part in the Welsh campaigns, which laid the Principality at the feet of Edward I. In 1285 Giffard bought the manor of Side from Simon Caleway, his kinsman, and settled it on his third wife, Margaret Neville. He died a peaceful death at his manor of Boyton in Wilts in 1298-99, and was buried at the abbey church of Malmesbury, leaving his son John, a boy of thirteen, a ward. John Giffard II., with his brother Edmund, visited the dying Abbot of Gloucester, John Gamages, in 1306, just as he (John Giffard) came of age. In 1316 he granted the privilege of free pasture in Buckholt to St. Peter's Abbey. He joined with Thomas, Earl of Lancaster, and so indeed did almost all the Gloucestershire nobility and gentry, in his struggle with the Despensers, and, like his leader, he was taken prisoner at the Battle of Boroughbridge in 1322. Lancaster was executed at Pontefract. Giffard was brought to Gloucester, tried and condemned as a traitor, drawn on a hurdle outside the town gates, hanged on a gallows and his body cut in quarters. In the previous year when Edward II. was at Cirencester on his march to the north, incensed because Giffard had waylaid and rifled some Royal carriages which were proceeding into Wales by the Ermin Street, he ordered Brimpsfield Castle to be destroyed, and so thoroughly was his order obeyed that in 1327 it was described as utterly ruined, and so Leland found it when he visited Gloucestershire in 1540. It was never rebuilt. Of course on the death of John Giffard his manors were confiscated by the Crown. Edward II. gave them to the younger Despencer, and, on his attainder, they were conferred on John Maltravers as a reward for murdering the king at Berkeley Castle. On his death they were granted to Maurice, Lord Berkeley, for his life, then to Lionel, Duke of Clarence, the third son of Edward III. By the marriage of his daughter and heiress they passed to the Earls of March and reverted to the Crown in the reign of Henry VIII., who gave Brimpsfield to Queen Katherine of Aragon. In the reign of Edward VI. it was granted to Sir John Bridges, afterwards Lord Chandos. In the reign of Elizabeth it was sold to the Sandys of Misarden, who again sold it to Dr. John Gilbert, archbishop of York, and it passed with his daughter in marriage to Lord Mount-Edgumbe. He sold it to the Pitts. It is now the property of Mr. Wait.

#### *Elkstone Church.*

Leaving Brimpsfield, the party drove along the wonderful old Roman road to Elkstone—a delightful journey, accomplished in beautifully bright and clear weather. When the church of St. John the Baptist had been reached,

The Rev. W. Bazeley described the structure, and pointed out its main features. He said:—It is a very curious church of Norman origin, and with a large portion of original work well preserved. The original plan is preserved—the nave without aisles, the chancel in two separate divisions and both vaulted, western tower and south porch. The walls of the nave and chancel and the south doorway are Norman; the tower is Perpendicular, and some later windows have been inserted. The original corbel table remains outside the nave, presenting heads, &c., and on the south are a greater variety of figures, such as winged horses, greyhounds, stags, centaurs, ox heads, an oblong chevroned figure, beakheads, &c. There is a billeted string-course and a flat buttress on the north. The masonry on the south has some zigzag work built into it. At the north-east of the nave is a small projection for the stairs, lighted by slits, leading to the chamber above the groining of the chancel, and perhaps to the rood-loft. The south porch is later and has a pointed doorway, but within it is a remarkably fine Norman doorway late in the style; the door-head is flat and shouldered. The tympanum represents the figure of our Lord, with Alpha and Omega, and a building in the background; on each side are ranged the Evangelistic symbols (or rather the ox, eagle, lion and a holy lamb), also scrolls and other figures. Above appears a hand as in the heavens, pointing to our Lord. The arch has two fine courses of moulding, one with rich beaded chevrons; one has a cylinder over which are curious animal figures and beakheads; in one instance a grotesque figure with extended hands is holding the beaks of the two adjacent figures. There are two orders of shafts: the outer having capitals of a kind of embattled pattern; the others have sculptured heads and serpents intermixed. The hood is beaded. There are some curious features about this doorway difficult to read. The chancel has walls loftier than those of the nave, but the roof is rather lower; both roofs are covered externally with stone tiles. In the nave the windows are insertions, chiefly Decorated, but one Perpendicular of two lights. On the south near the porch is a trefoil-headed lancet.

On the north of the chancel is a flat buttress and part of the original cornice, but intercepted. On this side is one small original window, and one inserted Perpendicular at the north-east. On the south are two single lancets, slightly pointed, and a later added buttress. Inserted in the masonry is a stone with interesting arches. The east end has two tiers of windows—the upper, of lancet form, lighting the chamber formed between the vaulting and the rafters; the lower, a small but very elegant Norman window, is enriched both within and without by a surrounding ornamentation externally of battlement. Above it externally is a billeted string-course, and below two buttresses of small projection. The nave has a good open roof, with collars and trefoiled timbers on brackets, bearing shields charged with arms and emblems. It is in good condition. The chancel, which externally has no indication of being divided, internally presents two divisions—a sanctuary and an ante-choir, both vaulted. The arch from the nave to the first portion is in form circular, the soffit plain; the hood facing west has balls or pellets, and rests on corbels representing animals like crocodiles, but not exactly similar. The ante-choir has the groining ruder than the sanctuary; the ribs very plain and simply crossing. Its north window is Norman, the south pointed, and on the north is the door leading to the upper chamber with flattened trefoil head. The second arch to the eastern portion is a low semicircular one, somewhat misshapen, whether originally or from having given way is uncertain. Its soffit is plain and carried on shafts with longitudinal mouldings—with one course of chevrons and a billeted hood. The sanctuary has strong ribs in the groining upon corbels, with a central boss, forming a kind of cusp, with heads, teeth, &c. The east window is set deep in the wall, and presents interesting ornamentation all around it, with bold chevrons containing lozenge-shaped flowers. The south-east window has in its east jamb a trefoil-headed niche and a piscina in the cill. There is some new coloured glass in the chancel window, and the ante-choir is used for the church choir. The pulpit is of fair woodwork, A.D. 1604, upon a stone base of earlier work. The font is Perpendicular, the bowl octagonal, panelled with quatrefoils, containing scrolls, with panelled stem. The tower is a very good Perpendicular one, opening to the nave by a tall pointed arch upon plain capitals, below which appear sculptured grapes in hollow mouldings. It has internally some good stone groining; the ribs are carried on shafts, which have on the capitals figures of angels bearing shields. The west window is a good one of four lights, with shafts having octagonal caps; externally it has the hood on corbels with angel figures, and against the central mullion is a large mutilated niche with canopy and the remains of a statue. The west doorway has a Tudor arch in a square. The buttresses on the north sides have grotesque figures, each of a fat man playing on a musical instrument—one a guitar, one blowing a horn. The battlements are good; there are no pinnacles, but gargoyles, buttresses at the angles and good base mouldings. The belfry windows are of two lights, with stilted shafts, the masonry being very excellent. The church and churchyard are in excellent condition.

#### *Cowley Manor.*

The stay at Elkstone was much too short for the party to sufficiently inspect the almost endless curiosities of the church, but time pressed, and the brakes were re-entered and the company drove to Cowley Manor, where they were cordially received by Mr. and Mrs. Horlick, who provided tea, after which the party walked about the delightful park, inspected its picturesque features, and went through the mansion, charmingly furnished, and with painted ceilings and rich mural adornments, which are being redecked by skilled artists. The manor of Cowley, formerly belonging to the Abbey of Pershore, was conferred by Henry VIII. on his new See of Westminster. It was held by the Bridges family in the commencement of the seventeenth century, and sold by them to Henry Brett, who built the manor-house in 1674. It was improved and richly decorated by Mr. Hutchinson some thirty years ago. The church of St. Mary the Virgin, adjoining the house, is all of Early English or thirteenth-century date, except the tower and porch, which are Perpendicular. The church is divided into two equal portions by a rood-screen, the stairs to which exist on the north side. A piscina, with a triangular-headed opening on the south side, shows there was an altar in front of the rood. The pulpit is Perpendicular. The piscina in the sanctuary on the south side is trefoil-headed with a shelf for the cruets. On the north side is a Decorated tomb, with the effigy of a priest wearing a chasuble, amice, alb, stole and maniple. Over the south porch is a niche for the statue of St. Mary.

#### *Coberley Church.*

The Rev. W. Bazeley having thanked Mr. and Mrs. Horlick for their kindness, the vehicles were entered again, and the party drove to Coberley, where they were received at the church by the rector (the Rev. C. H. Wilson), who pointed out the

chief features of the edifice. The church of St. Giles (formerly St. Cuthbert), Coberley, consisted before its restoration of a nave, chancel, south chapel, west tower and south porch. The whole of the church, except the tower and porch, which were Perpendicular additions, was fourteenth century or Decorated. As at Cowley, there was no chancel arch; the rood-screen was the only division of the choir from the nave. Within the altar rails, north and south of the high altar, were two recumbent effigies. These are now in the south chapel. These effigies probably represent Thomas de Berkeley, who fought at Crecy, and his first wife, whose name is unknown. These were placed originally in the sanctuary, because Thomas de Berkeley rebuilt the church and founded a chantry for the service of St. Mary, about the year 1340. There is also a smaller recumbent effigy of a young girl in hood and gown, with a buckled belt around her waist and a lion at her feet. It probably represents a daughter of Sir Thomas Berkeley. There is also a curious half-figure of a knight in mail holding a heart. This has also been removed from the sanctuary to the south chantry chapel. A fifth effigy represents a youth in the dress of a civilian, a tunic, long gown, supertunic and a hood. This is probably a member of the Berkeley family, who died at the latter end of the fourteenth century. Between the two Decorated windows on the south side of this chapel is a low side window, the use of which is unknown. It is not a leper window, for no one looking through it from outside could see the celebrant either at the high altar or the chantry altar. A high wall on the south and east of the church, with two Renaissance doorways, is all that remains of the manor-house of Cubberley, where dwelt the Berkeleys, the Bridges, Sir Thomas Pope, Earl of Down, who more than once entertained there Charles I., and the Castlemans. An engraving of the house and church, as they appeared at the commencement of the eighteenth century, is given in Atkyns's "Gloucestershire." Charles II. spent a night in Cubberley Rectory on his journey from Boscobel to Abbot's Leigh, after the Battle of Worcester. The rector showed in the chancel floor the memorial-stone of the past rectors of Coberley, all of whom appear to have reached a very ripe age, the eldest being Lewis Jones, who died on July 29, 1651, aged 105.

#### *The Berkeleys.*

The Rev. W. Bazeley gave a brief account of the Berkeleys, and pointed out that there were two families. The Berkeleys had a castle at Dursley and a smaller one at Berkeley, the hundred of which they held at the time of Domesday Book, and for several generations. But in the time of the civil war between Matilda and Stephen they were dispossessed. Henry II., before he became king, promised the hundred of Berkeley to Fitzhardinge, who was then a kind of mayor of Bristol. The Berkeleys of Berkeley Castle were lineal descendants of Fitzhardinge, who came into the estate at the time of Henry II.; but the old family was not ruined, because an arrangement was come to by which the son of one family should marry a daughter of the other, or *vice versa*, and the two families became united in this way. Dursley remained with the old family branch. The Thomas de Berkeley who fought in the French wars with Edward III. was one of the most celebrated warriors of that time, and was no doubt joined by many skilled archers of Gloucestershire, who helped to turn the battle to the side of the English. The reason why there were so many yew trees in the churchyards of Gloucestershire was to provide the villagers with the material with which to make their bows and arrows. The second branch of the family were the founders of the family of Chandos, and at one time there lived at Coberley the richest and grandest people in the West of England. Sir Giles de Berkeley left his body to be buried in the chancel of Malvern Priory and his heart to be buried in the chancel of St. Giles, Coberley. King Charles II., during his flight from Boscobel, stayed at Coberley and slept at the rectory, whence he passed in disguise through the county to Abbot's Leigh, near Bristol. He ultimately reached a southern port and escaped to France. The notion that May 29 was celebrated as oak-apple day because the king concealed himself in an oak tree on that day was not correct, but because when he was restored that was the date of his restoration. He hid in an oak tree three or four months later in the year than May. Having pointed out the doorway, the only part of the manor-house of Coberley, Mr. Bazeley, addressing the company, expressed his thanks, on their behalf, to Mr. and Mrs. Horlick for their kind reception and entertainment, and mentioned that Mr. Crewdson, of Side, had invited the party to luncheon, but he had declined. The reasons were because he thought it unfair, considering that he had been but a short time in the county, that he should be put to the expense and trouble attendant thereon, and because too much time would be occupied thereby. Mr. Bazeley also expressed his thanks to Mr. Currie for the assistance he had rendered.

It was nearly half-past seven when the company joined their respective vehicles and were quickly driven to the railway stations to catch trains or to their various destinations direct.

The trip proved one of the most enjoyable and instructive in the annals of the Society. The report is taken from the *Bristol Times and Mirror*.

### MODERN VAULT CONSTRUCTION.

THE ordinary portable burglar-proof safe is the type of the burglar-proof vault. Vaults indeed are distinguished chiefly by their size; a vault is a safe big enough to walk into, with other minor differences that we shall hereafter note.

Ordinary portable safes are of various sizes up to about 6 feet width of front and 7 feet height. The depth inside in the clear, even of large safes, must not exceed the reach of a man's arm, which means about 3 feet depth outside, owing to the thickness of the walls and doors and the space required for the mechanism.

Vaults proper, such as are large enough to walk into, are usually 8 feet high inside and as large as required on the floor—seldom less than 8 feet square, and seldom needed more than 8 by 16 feet for the use of banks.

Safe-deposit vaults are often built of great size, 40 feet square or more; the height, however, does not exceed 8 or 8½ feet.

With the portable safe we have not much to do at present, as it is only when the safe has grown to the dignity of a vault in size that especial provision need be made for it by the architect.

In arranging a place for the vault, whether of a bank, safe-deposit company, or other concern needing one, the first consideration is to place it clear of contact with the building on all sides. A space wide enough for convenient passage at least must be left all around the vault; a similar space between the top of the vault and the ceiling of the room in which it stands; while the space in the room below the vault must also be open for continual inspection. Often an open grating in the floor surrounds the vault, making it possible for a patrol to watch the whole circuit in two storeys at once. When this is done the bars of the grating must run in the direction of the path of the patrol to permit an easy view.

This matter of the isolation of the vault, although often neglected, is a fundamental requirement for safety.

The next thing to be looked out for, trivial as it may seem, is the swing of the entrance door. In the first place, the throw of a vault door is very much greater than the width of the clear entrance. If the inside entrance door is to be 2 feet 6 inches wide, clear of the bolt work, we must add to this about 3 inches for the bolt work, as much again for the opposite rabbetted jamb, and again another foot for the splayed, rabbetted jambs of the outside door. Add to this several inches more for the working of the mechanism of the hinges, and we have 4 feet 6 or 8 as a minimum throw of the outer door to be provided for. Again, it is quite usual to place the floor of the vault a foot or so below that of the room in which it stands. This is done so as to bring the highest point of the rabbetted sill low enough to allow a movable platform to be placed over it, terminating in an easy slope inside the vault. This is done to do away with the annoying and dangerous stumbling-block that would otherwise be formed by the rabbetted sills of outer and inner doors. It is one of the standing difficulties in the use of vaults, so much so that a movable sill, which lies down flat, out of the way, has been invented and may be used. But, when this is not used, the lower edge of the outer door will swing below the level of the floor of the room, and provision must be made for it.

Finally, all vaults must stand on a foundation of their own; not on beams, however strong. Beams are sure to bend a little, and the slightest bending will throw the swing of the great doors out of true, so that it will be impossible to open and close them. Besides, the tremor of a floor would tend to disturb the mechanism of the time-locks. Moreover, to stand a vault on a floor makes the integrity of the vault depend upon the stability of the building; a fire, or earthquake, or explosion, or unaccountable fall of the building would carry with it the vault, which might be penetrated in the crash. So it may be laid down that a foundation of its own a vault must have, preferably of brick arches. We shall again allude to foundations after we have spoken of the construction of the vault itself.

In planning a safe-deposit vault much more careful provision is required than for any other kind. The arrangement of the interior depends upon the placing of the banks of small safes with which the vault is to be filled. These safes are of a regular depth, usually 2 feet, whatever may be the size of the door in the face of the stack. The passages between the stacks should not be less in width than 3 feet, nor greater in length for a *cul de sac* than 10 feet. This for two reasons, partly for ventilation, as the air is apt to stagnate in long blind passages, partly to avoid undue interference and jostling among the depositors.

The placing of the entrance and exit is determined by the general plan of the offices, and upon this, in turn, depends the laying out of the passages and banks of safes inside.

Every safe-deposit vault must have two entrances, each complete, with vestibule and outer and inner doors, as will be hereafter explained. The most economical form of vault is about 8 feet wide, with a door at each end, and banks of safes on each side. Up to 20 or 25 feet in length, this will do very well.

Beyond this some form of square or oblong vault, with transverse secondary passages branching from the main passage must be used, as the single straight passage begins to pass reasonable length.

Two entrances are essential for safe-deposit vaults on account of the ever-present possibility of an accidental lock-out caused by defect or stoppage of the time-locks. With banks a lock-out is disagreeable enough, but for a safe-deposit company, with hundreds of concerns wanting to get at their deposits, such an occurrence would be fatal. Two entrances render the chance of an accident to both at the same time infinitesimal.

Indeed, it would always be well, were it not for the cost, to provide bank vaults and all kinds of vaults with two entrances. On account of the cost, however, this is rarely done. Various expedients are resorted to with the same end. I have designed two vaults alongside each other with a hole in the partition wall, usually covered by a steel-plate cover, secured by bolt work and locks, but serving to give access to either safe from the other in case of a lock-out. A similar design I have made in two storeys, with a hole in the floor between, similarly made secure.

Another continual care of safe-deposit officers is the ventilation of the vault. The unavoidably contracted space, with many people frequenting it, and only two doors giving admission to the outer air, is sure to make trouble.

The best thing to do, although costly, is to make one or more holes in the ceiling of the vault, with covers fitted precisely as the doors are fitted that can be lifted by screw or other power while the vault is in use, and closed at night and bolted inside.

Such an opening, enclosed in a sheet-metal trunk, may be connected with a Blackman-wheel air-current, and the interior of the vault supplied with abundance of fresh air.

The use of electric lights has simplified the question of vault ventilation, which in the days of gas light was an almost insoluble problem.

For both safes and vaults there is one predominant method of construction; there are, besides this, half a dozen other methods more or less in use.

The usual way is to build up the required thickness of the walls with plates of steel screwed together. These plates vary from half an inch to 2 inches in thickness. Half-inch plates are commonly used, with an inch plate on the outside, because such a construction is much cheaper than the same thickness of walls built up with inch plates throughout. Inch plates are stronger and better construction, but half-inch are very good and quite usual.

The plates are not generally all of the same material. Steel, indeed, they all are, but the alternate plates are usually of chrome steel.

Nor are these chrome steel plates simple; they are in themselves compound, each plate being built up of five plates, rolled together hot, welded into one mass, the central and interior layers being of ordinary homogeneous Bessemer steel, the intervening two layers, making five layers in all, of chrome steel proper.

Chrome steel has a small proportion of chromium added, which gives to it an excessive hardness against attack by the drill—nothing but diamond drills and plenty of time to use them will cut it. By the use of the blow-pipe, however, the temper may be drawn, and it is then drilled with as much ease as other soft steel. It is rolled in layers, as described, because with extreme hardness there is an accompanying lack of tenacity which the layers of ordinary steel are intended to supply.

The plates that are not chrome steel are of the usual mild steel, which is so fast supplanting iron, being both better and cheaper, rarely as those qualities are found together.

The plates are fastened together by screw bolts screwed in from the inside. These are not long enough to penetrate the outside plate; they give no indication of their position. The bolts that secure each succeeding plate are carefully laid out so that no two bolts occur at the same point.

The whole vault is built up in the shop of untempered plates screwed together just as it will be in the bank, safe-deposit office or other institution for which it is destined. It is then taken apart; the plates are tempered and afterwards straightened before they are taken to the place where the vault is to be built.

The walls of vaults vary in thickness. Three inches is a good thickness, four inches ample, and the thickest built, so far, is six inches thick.

\* From a paper by Mr. John Beverley Robinson, architect, in the *Architectural Record*.

All vaults of any pretension at all are provided with a double set of doors at the entrance—with what is called a vestibule. The vestibules may be deep enough to contain the whole of the inner door when open, or may be only deep enough to accommodate the knobs and levers of the inner door and the bolt work on the inside of the outer door when both doors are shut. In the former case it is possible to make the opening of the outer doorway no larger than that of the inner—in the latter case the outer doorway must have additional width enough for the inner door to stand out at right angles.

The clear width required for the inner doorway is not less than 2 feet 6 inches nor more than 2 feet 10 inches. Both outer and inner doors are by preference single doors, because such can be made stronger than double doors; often, though, for convenience the inner doors are made double, one opening into a pocket on each side of the vestibule.

Both outer and inner doors fit into their jambs with rabbets and grooves. Each steel plate of which the door is composed sets back from that outside of it, and if more than half an inch thick is itself rabbetted in its thickness in half-inch steps. Besides these rabbets there are used in each door usually two groove irons, as they are called, really angle irons; for thick doors three are used, but rarely less than two, for in addition to the rabbets, and as far more efficient, the grooves are depended upon to exclude explosives. For still more perfect protection the edges of the angle irons are corrugated, and in the bottom of the opposed groove is placed a strip of rubber or asbestos packing upon which the sharp edges of the corrugations press tightly and form an air-tight joint. This closeness of joint is especially meant to keep out nitro-glycerine, which is used in liquid form in the attack.

Two things are needed for the attack—force and time. The force must be such as can be used quickly. Drills are all very well, but wedges, driven by a copper-headed sledge, which makes but little noise, start the edge of a plate more quickly. Into the minutest crevice a little nitro-glycerine penetrates, drawn into incredibly small space by capillary force. The explosion tears away more or less of the plate, leaving the next joint exposed for the wedge.

When the circumstances prevent the use of explosives the drill and the hydraulic ram are resorted to, but for speed and force combined explosives are preferred.

The noise of the explosion, muffled by the walls of the building in which it occurs, to outside ears seems to passers who may happen to notice it like some distant report, or often attracts no notice at all. For this reason it is often possible to use explosives where it would seem to be impossible without immediate discovery.

Nitro-glycerine is the agent most feared nowadays. It will penetrate any joint, and at least relax it with its tremendous shock, giving space for the introduction of a heavier charge. Although dangerous to make and difficult to buy, it is easily obtained from ordinary commercial dynamite, which is nothing more than nitro-glycerine held in absorption by infusorial earth or other absorbent. The liquid nitro-glycerine is obtained by the simple process of dissolving it out with 95 per cent. alcohol, and then precipitating the nitro-glycerine by the addition of water.

In order that doors constructed as has been said with rabbets and grooves may be opened and closed, something more than ordinary hinges is clearly required. Something it must be that will move the whole door parallel to itself a distance equal to the depth of the grooves and rabbets, in most cases, that is to say, half an inch. To do this several kinds of crane-hinges, as they are called, have been devised, which accomplish their purpose admirably. Not a trifling matter this either, to wield at the end of a rotating arm, to suspend upon it in a position where it can easily be moved backwards and forwards, and yet is so firmly immovable otherwise as to fit with accuracy into its complicated seat, a weight not less than 4 tons, often 6, and sometimes as much as 10.

Although the weight of the heaviest vault is trifling compared with the weights that architects are accustomed to deal with in building, yet certain precautions are necessary in providing foundations for them. The vestibules especially must be upon an immovable base, for the slightest sag or settlement means a distortion of door-jambs, and the impossibility of closing the doors. The bottom of the vault, although amply strong enough to sustain itself over ordinary spans, say up to 10 feet, is apt to sag slightly in reaching its point of resistance, and is better supported by rolled beams placed 3 to 4 feet apart. These must be adequately supported by columns, piers or walls, for the vault must not rest upon the earth directly, as such a situation invites attack by tunnelling from a distance, which can be carried out with perfect security, as observation is in such an arrangement impossible.

Therefore all vaults are on some kind of open foundations, usually extending through a basement, and supporting the vault level with the floor above. Sometimes these foundations are in the form of a brick vault, less secure than the steel vault above, but sufficient for the storage of silver, paintings and valuable

books. In this case the brick vault has a door like that of the steel vault, less ponderous perhaps, but substantially the same thing.

But if used for this purpose the foundation should be as open as possible, the walls perforated with arches everywhere. Brick walls are much to be preferred to iron columns, as less likely to be destroyed by fire.

Columns, if used, should be securely covered with fireproof material, as also should any iron columns that support the floor of the vault.

For supporting the floor brick vaulted arches, dispensing with iron altogether, are as much to be preferred as brick walls are to iron columns.

The ceiling of the vault up to 8 or 10 feet span will sustain itself. For wider spans some interior support must be provided. This is often furnished in safe-deposit vaults, which are the largest vaults in use, by the banks of small safes with which the vault is occupied.

These, however, are not usually put in all at once when the vault is built, but gradually as the business requires; because often the character of the business requires a change in the style of safe used, or new inventions must be included to make the safes rentable.

Until the banks of safes are put in it is usual to support the ceiling of the vault by small cast columns or pieces of wrought-pipe. The ceiling is jacked up the half or three-quarters of an inch necessary, and when it comes down it holds the column firmly in place.

When the ceiling must be carried without columns over a clear span the steel beams necessary to carry it are placed outside, above the ceiling to be carried, and the outer shell is attached by conical eyebolts and suitable hangers to the beam. It would be as well or better to put the beams inside were it not for the valuable space they would occupy.

Vaults are usually made only 8 feet high in the clear, because of the great cost of every added inch, and beams inside would cut this down, both for use and looks, very materially.

The steel walls of the vault itself afford sufficient support for the suspended ceiling without special provision in addition.

Thus built and upon such foundations stand some vaults, good ones at that, without defence against fire at all, being in buildings called fireproof, and certainly unflammable in their constructive parts.

It is better, however, in all cases to provide some kind of fire-resisting jacketing. Of this, two kinds are commonly used. Nothing is better for fireproofing than a brick wall. It should be hollow, if possible, with two 8-inch walls or an outside 8-inch and inside 4-inch at least. The ceiling must be covered with at least four courses of brickwork.

All should be laid in good cement mortar, although lime mortar gauged with plaster of Paris might be even better than cement. In a combustible building, at least, this covering of the ceiling should be in form of brick arches, laid between iron beams placed on the top of the vault, with the usual tie-rods, and made as strong as possible, to resist crushing by a falling wall if fire should occur.

The great objection to brick walls is the space that they occupy. Two 8-inch walls with a 4-inch space will be 20 inches, and this carried around a vault of 50 feet circuit covers about 83 square feet—a considerable space where space is most valuable. So sometimes the fireproofing is done with a covering of concrete—cinders, plaster and cement, mixed and filled in between the outside of the vault—and a quarter or three-eighths inch plate of soft steel held to the shell of the vault by anchors at frequent intervals.

## TESSERÆ.

### Decline of Art in Egypt.

AT the period of the Persian invasion, Egypt was looked upon as the great school of science, and the repository of all kinds of learning; but the arts had fallen from the degree of excellence to which they attained under the Augustan age of the eighteenth dynasty, and, though luxury and private wealth increased, taste in sculpture and architecture had long since been on the decline, and minute and highly finished details were substituted for the simple and dignified forms of an earlier period. The arts, however, continued to flourish under the succeeding dynasties, and in the reigns of Psamaticus and Amasis the encouragement given to architecture, sculpture and painting seemed to promise an improvement, if not the revival, of taste, and arrested for a time their downfall; but an unexpected event was destined to bring about their sudden decadence, and the Persian conquest dealt a blow from which they vainly strove to recover in the succeeding reigns of the Macedonian dynasty, for not only were the finest monuments destroyed or mutilated, statues, works of art and all the wealth of the country carried off to Persia, but the artists themselves were compelled to leave their homes to follow the conquerors to their capital, and to commemorate the victories obtained over Egypt

by the authors of their own captivity and misfortunes. Thus deprived of the finest models, humbled by the lengthened occupation of the country, and losing the only persons capable of directing taste or encouraging art, Egypt, already beginning to sink, vainly endeavoured to struggle with the overwhelming current of events; and, while Persia was benefited, Egyptian art received its deathblow from the invasion of Cambyses. The Egyptians had long been renowned for mathematical science, but it was not till the power and wealth of the country were at their zenith that full scope was given for its display in the grand style of public monuments; a fact sufficiently indicated by their increase of scale and vastness of size at that period, the buildings of olden time being generally of much smaller dimensions than those of the advanced age of the eighteenth dynasty. This is particularly true of the temples and the colossal statues erected at the latter epoch, which far exceed in their scale, and the size of the blocks themselves, the ordinary monuments of the earlier era, as may be observed in the increased proportions of the grand hall of Karnac, added by Rameses the Great, and the dimensions of the sitting colossi of Amunoph in the plain of Thebes; or that of Rameses at the Memnonium, which weighed about 886 tons, and was brought overland from the quarries at the cataracts of Syene, a distance of more than 120 miles.

### De Louthembourg and the English Stage.

De Louthembourg, decidedly the prince of scene-painters, had contributed largely to the improvement of the stage. Garrick, whose judgment was equal to his liberality, engaged him as principal painter for his theatre, at a salary of 500*l.*, a much larger sum than had been afforded to any of his predecessors. It was from this epoch we may date the superior decorations of dramatic exhibitions; for before the arrival of this ingenious artist, not only little attention had been bestowed on the scenic department, but even the costume of the stage had been a matter of minor consideration. Indeed, the anachronisms of dress which were tolerated at the principal theatres, if reintroduced in this more enlightened age would, without the necessity of exaggeration, be viewed by the more illiterate among the playgoers as complete burlesque. Hogarth had already given his friend Garrick some satirical hints upon the subject in the plates of his "Analysis of Beauty." But it was left for De Louthembourg to urge, and finally complete, the desired reformation.

### William Hogarth.

As an inventor Hogarth is by far the greatest of the British school, although in aim and object, colour, surface and all the requisites of a great painter, infinitely below Reynolds. It would be useless to detail the perfections of a man so admired all over the earth, and who will only cease to be a delight with its existence. It is astonishing how hereditary is the hatred of academies. The painters, in revenge for Hogarth's opposition, swore that he was no painter, and swear so to this hour. The absurdity of this criticism can be proved by the *Mariage à la Mode*, whilst the picture of the husband and wife after a rout is as beautifully touched as any in that class of art can be. He has not the clearness of Teniers nor the sharpness of Wilkie, his touch is blunt and his colour deficient in richness, but you feel not the want whilst looking at him; and, although his expression is often caricature, yet in the above picture it is perfection. Hogarth, unfortunately, believed himself infallible, but his wretched beauty of Drury Lane for *Pharaoh's Daughter* at the Foundling, his miserable *Sigismunda* and his was serious *Felix*, we hope, convinced him of his *forte*. If he *Paul before* in these pictures, which we very much doubt, he deserved a strait waistcoat and a low diet as the only treatment for his hallucination.

### Wimbledon Tendering.

SIR,—We shall be glad if you will allow us space for drawing attention to the following facts, for although it may be considered a private matter so far as it concerns ourselves, yet as it involves an excess in the expenditure of the rates to the amount of 70*l.*, you may deem it something more. Some few weeks since the Wimbledon Urban District Council advertised for tenders for the erection of an underground convenience to be constructed in the Broadway. Plans and specification were to be seen at the Council offices. Having inspected the same, we determined to send in our tender, and upon asking for the usual copy of the specification and bill of quantities, we were informed that the latter must be got out by ourselves, and that the former could only be seen in the office. Not deterred at this, we went fully into the details and took out the quantities,

with the result that we sent our tender in by the appointed time, May 17, our price being 545*l.*, which sum included the builder's usual profit and the surveyor's fixed amount of 25*l.* to be expended for Doulton's and other special appliances which the Council had determined upon. Seeing by the report in the local papers that two tenders had been received, and that it was decided to invite tenders from other firms, we waited upon Mr. Cooper to ask for some explanation, and if the tenders sent in had been opened, and learnt from him that the tenders had been opened and that he had written to one other firm only, a London firm, both the tenders received being local. In the reports of the Council meeting of June 2 will be found the amounts of three tenders as follows:—

Jennings, London . . . . .	£615 0 0
Burgess, Wimbledon . . . . .	614 0 0
Dashwood, Wimbledon . . . . .	545 0 0

the highest being accepted, subject to approval of proposed fittings. The above facts suggest two questions, and possibly a third. Why were the local firms *limited* to certain special fittings and tiles, and after their prices were known the London firm allowed to choose what they would use, subject to the surveyor's approval? Why spend 615*l.* in London when 545*l.* to a local firm would have given the town the very best structure it is possible to build, for it was such we estimated for and intended to give for our own credit's sake, and some of the prominent residents of the district, for whom we have the pleasure of working, are ready to testify to our ability to carry out our contracts? Having been ratepayers in Wimbledon since 1882, when we erected our horticultural and building works, we think you will feel with us that we have been treated as bad as the rates, which are to be wasted to the amount of 70*l.*—Yours faithfully,

ARTHUR DASHWOOD & SONS, LIMITED.

June 8, 1897.

### GENERAL.

**M. Falguère** has obtained the commission for the statue of M. Pasteur which is to be erected in Paris and which will cost over 10,000*l.*

**The Slade** Professor of Fine Art in Oxford will deliver the remaining lectures in this term upon the "Sphere of Paduan Influence" as follows:—Friday, June 11, "Carlo Crivelli;" Saturday, June 12, "Alvise Vivarini;" Thursday, June 24, and Friday, June 25, "Paduan Influence in Lombardy—Vincenzo Foppa and his Pupils." The lectures will be given in the lecture-room of the Ashmolean Museum (University Galleries), at 4 P.M. each day.

**Mr. A. C. Gow, R.A.**, has been commissioned to paint the picture illustrative of Her Majesty's visit to the City on the 22nd inst., of which Mr. Henry Clarke, L.C.C., is the donor. When completed it will be deposited in the Guildhall Art Gallery. The point which has been determined upon for the picture is the Queen's arrival at St. Paul's Cathedral, followed, as Her Majesty will be, by the mounted princes and by the Lord Mayor, the background being occupied by the edifice itself and by the assembled clergy.

**Mr. T. P. Martin**, architect, Swansea, died on Sunday last.

**Mr. F. J. Warden-Stevens, A.M.I.E.E., &c.**, of Westminster, as we announced in a previous issue, had been appointed consulting engineer to the Poplar Guardians, in connection with the electric lighting. He has since been requested to prepare a complete scheme for steam supply and storage, supply and storage of water, and motive power arrangements.

**The Ground** in North Bridge Street, Edinburgh, which is available for building sites owing to the construction of the new bridge, is to be sold in one lot by auction, the reserve price being 200,000*l.*

**Lauderdale House**, in Aldersgate Street, is about to be taken down, in order to provide a site for the new works to be erected by Mr. H. C. Stephens, M.P.

**The Ancient** and royal castle of Tamworth, the property of the Marquis Townshend, was offered for sale on Tuesday at Tamworth town hall. The town clerk, on behalf of the Corporation, began the bidding at 1,000*l.* Other bids were made, and the town clerk eventually bid 3,000*l.*, at which figure the property was declared to be bought by the Corporation.

**Mr. Thackeray Turner** says that the Society for the Protection of Ancient Buildings are considering the work at Canterbury Cathedral, and, however much the public may appreciate work done under Sir A. Blomfield's influence, "it is questionable whether they are willing to lose original Mediaeval work to make way for it. Upon entering the chapter-house, everything which meets the eye gives the impression of newness, with the exception of the existing flooring, which is made up of monumental slabs and plain red tiles, and this we understand is to be entirely replaced by a stone pavement. As one of our informants said, 'It is entirely like entering a brand new building.'"

# The Architect.

## THE WEEK.

THE memorial of Lord LEIGHTON in St. Paul's is to be in the form of an altar-tomb supported by emblematic figures. Mr. THOMAS BROCK, R.A., will be the sculptor. The design has been approved by the Prince of WALES, the president of the committee and the members. The work will cost 2,500*l*. The subscriptions amount to 2,400*l*., and an appeal is made to the friends and admirers of the late President of the Royal Academy for the small sum which is still required. When Lord LEIGHTON died it was anticipated that a liberal amount of money would be forthcoming as an expression of the grief which was generally felt at the loss of a general favourite and of an artist whose aims were not restricted to the obtaining of large sums for his works. But there was practically no response to the proposal to purchase the President's house at Kensington, and the subscriptions for a monument are not remarkable. The results are a comment on the real value of public favour.

It is, we suppose, no more than natural that, out of loyalty, efforts should be made to demonstrate the progress of England during the reign of HER MAJESTY by contrasting the year 1897 with 1837. A comparison of that kind cannot always be true in the case of the fine arts. Under the most auspicious conditions great artists cannot be created. They are born, not made. On the other hand, they often appear at times when they seem to be out of place, for their contemporaries cannot understand them. Numerous as were the shortcomings of the people in 1837, if judged by the standard of the present year, it cannot be denied that artists who would have honoured any era then lived in England. It was the year when TURNER exhibited that view of Venice for which a few weeks ago over seven thousand pounds were paid. Among his other works then seen were the *Parting of Hero and Leander* and *Apollo and Daphne*. EDWIN LANDSEER was represented in the Royal Academy by several of his most popular works—the *Shepherd's Chief Mourner*, the *Return from Hawking*, the *Return from Deerstalking*; WILKIE by his *Cotter's Saturday Night*, MACLISE by his *Bohemian Gipsies*, LESLIE by his *Perdita*, ETTY by his *Sirens*, and J. F. LEWIS by his *Spy and Zumalacarre*. Some of those pictures are now national property, and they are evidence that the painters' art was not at a low level.

THE Institute of British Architects was not in 1837 entitled to prefix the word "Royal" to the name, but Lord MELBOURNE, as Prime Minister, was able to inform Lord DE GREY, the president, that HER MAJESTY had graciously consented to become patroness of the Institute. Sir ROBERT PEEL was elected an honorary fellow. The honorary secretary was then T. L. DONALDSON, who was busy with projects. One was a universal system of architectural notation. He showed how out of twelve writers on Greek architecture five had distinct methods of notation; of those on Roman architecture, two only had given dimensions in feet and inches, and both used different modes; and among the several writers on Gothic architecture the systems adopted were as numerous as the writers. He proposed that the feet and inches be separated by two strokes, as in our monetary system, and that the parts of an inch should be expressed decimally by a dot; that the symbols should be those used by astronomers—the small circle for the feet, as the primary quantity, the simple stroke, or acute accent, for the inches, and the double stroke for the tenths, thus: 1'; 2', 5". No confusion could arise from the employment of the astronomical symbols, as temples, and even cities, are never measured by degrees of miles; and it was recommended that the scale should always be placed at the bottom of a plate, and the different divisions carefully marked thereon. It would appear that the first example of a fitch beam was shown at one of the meetings during the year. It was said to be the invention of Mr. JOHN MARTIN, and consisted

merely of a thin plate of wrought-iron, which passed through the rollers, screwed tightly between two three-quarter deals; and several experiments were made on a small scale to show what great strength was gained by the arrangement.

THE prizemen of the Royal Academy in 1837 did not fulfil the expectations that were founded on them; for instance, the gold medals were awarded to E. B. MORRIS for the best original painting, and to JOHN A. GIFFORD for the best original design in architecture. The silver medals were gained by J. HAYES for the best copy in the Painting School, SAMUEL TAYLOR for a copy in the Painting School, T. H. HARLAND for the best drawing from the life, THOMAS BURTON for a drawing from the life, W. SNOOK for an architectural drawing, A. J. ASHTON for the same, J. RIVERS for a model from life, W. CARPENTER for a drawing from the antique, H. LE JEUNE for the same, NELSON O'NEAL for the same, G. NELSON for a model from the antique. Among so many successful students Mr. LE JEUNE alone attained the rank of associate. Mr. ASHTON, we believe, practised as an architect, but the remainder have left nothing which will preserve their names from oblivion.

FREEZING is occasionally employed in the north of Europe as an auxiliary in the carrying-out of foundations. The first application was in the Siberian mines. In order to reach the gold-bearing rock, which is in many places beneath strata of gravel and sand containing watery seams, the natural cold of the winter season is turned to account. The ground is kept clear of snow, so as to permit the cold to penetrate as deeply as possible, after which the surface is thawed by fires until a shallow layer of earth can be removed. The freezing is then allowed to proceed and the thawing operation repeated, and this is continued as long as the cold weather lasts. In this way, through the long Siberian winters, open excavations are made to the gold-bearing rocks, the depth attained being from 25 to 75 feet, according to the duration of the cold season. Artificial cold for purposes of excavation was used first by POETSCH in 1883. By his process of the circulation of cold brine through a series of buried pipes, the most difficult quicksand may be made hard enough to be excavated like rock. It was used in sinking the shaft at the Courrières mines. Among the applications of the freezing-process are the sinking of the shafts for the cylinders of the hydraulic elevator for the canal lift at Les Fontinettes, and the construction of a tunnel at Stockholm. The latter work was executed entirely by the introduction of cold air into the working-chamber at the head of the tunnel, the cold preventing the infiltration of water until the béton lining was built and the work of excavating and lining being carried on at temperatures ranging between 0 deg. and 25 deg. F.

THE statistics furnished by Mr. T. W. RUSSELL, M.P., at the dinner given by the British Institute of Public Health on Wednesday were remarkable. Whilst in the twenty-four years preceding 1873 the local authorities in this country spent 11,000,000*l*. upon sanitation, for the twenty-four years following that date the expenditure was 72,000,000*l*. When examined in detail the figures were equally interesting. In 1872, for example, 103 loans were sanctioned to public authorities for sewerage, water supply purposes, &c., the total amount being 445,000*l*. In 1896 the loans had risen to 596, and the amount to 2,830,000*l*. In 1872 all that any local authority in England and Wales spent on infectious hospitals amounted to 3,970*l*. Twenty-four years later 132,000*l*. was so spent. The amount expended in 1872 by public authorities in the disposal of house refuse was 700*l*. In 1896 the expenditure amounted to 120,000*l*. In 1872 fifty local authorities adopted sewage schemes, but in 1896 the number rose to 300, and the expenditure showed an increase from 310,000*l*. to 1,484,000*l*. In that year, too, no less a sum than 3,000,000*l*. had been expended under the Housing of the Working Classes Act of 1890. Although so much has been done further expenditure is needed, but apparently the improvement in public health keeps pace with the outlay.

## ST. PAUL'S CATHEDRAL.

WHEN studying the history of the cathedrals, abbeys and the greater Mediæval churches of England, it is often difficult to decide how far the bishops and other clerics who are recorded as the architects of the buildings corresponded with the men who now practise the art. At all times a bishop's office was onerous, and as far as can be made out an abbot's or a prior's was as little of a sinecure. If they faithfully discharged the duties laid on them their hours must have been fully occupied. On the other hand, architectural practice could not ever be considered a pastime. To build a cathedral or church which abounded in constructive difficulties—for in Mediæval days it was almost necessary to arrange the masonry in such a way as to amaze the uninitiated and to surprise experts by novelty—was not a hobby to be taken up in moments of relaxation. Apparently there must be a sacrifice of one office to another, or a compromise which would hardly befitt the holder of an ecclesiastical dignity. There is nothing to show that JOHN ALCOCK of Ely, RICHARD BEAUCHAMP of Salisbury, ROGER GROSTETE and HUGH DE GRENOBLE of Lincoln, WALTER SKIRLAW of Durham, WILLIAM WAYNFLETE and WILLIAM WYKEHAM of Winchester, GUNDULPH of Rochester, or OSMUND of Sarum were negligent as bishops. Tradition is also silent about the monks of Ely being free from discipline whilst ALAN DE WALSINGHAM was calculating the thrusts of the central lantern—a problem as onerous as that of the cantilevers of the Forth Bridge in our days. Prior BIRD ruled in Bath during the time the noble abbey was in course of erection, and the novel feats of vaulting and over-elaborate carving in the Chapel of HENRY VII. went on while WILLIAM BOLTON, the master of works, presided in St. Bartholomew's, Smithfield. It is not easy to obtain coadjutors in high ecclesiastical offices; and would it not be then safe to conclude that the architectural works were entrusted to deputies? When we see RICHARD DE GAINSBRO' represented in the Lincoln cloister holding a rule and compasses, we must conclude he was known to his contemporaries as a designer; and when we learn that HENRY the monk, who is credited with Evesham Abbey, was called "latomus," we assume he was a practical builder who was able to draw plans as well as cut stone. But for the majority of the ecclesiastics we have not even such evidence of connection with architecture as is afforded by a symbol or a nickname, and it would not be unreasonable to suppose they were administrators rather than architects of the modern type. The Mediævalists may have been superior to us, but they did not possess means to facilitate the acquirement of skill in design or a comprehension of the science of construction. To them as to us, architecture was full of mysteries which could only be revealed by long and patient labour.

It is remarkable that when, after a long period, it was necessary to erect a new cathedral, or, in other words, only two centuries ago, there should be almost as much uncertainty about the position of the architect as if he had lived in the thirteenth century. The inscription in St. Paul's Cathedral tells the visitor that if he wishes to discover the tomb of the builder of the church he has only to look around—"Lector, si monumentum requiris, circumspice." And HORACE WALPOLE says:—"A variety of knowledge proclaims the universality, a multiplicity of works the abundance, St. Paul's the greatness of Sir CHRISTOPHER'S mind. Our noblest temple, our largest palace, our most sumptuous hospital are all works of the same hand." All that is admirable rhetoric and it conquers the imagination. But the fact remains that we cannot say whether WREN drew one of the numerous mouldings in the cathedral or designed one leaf of the ornament. There must have been an organisation for designing and drawing over which he presided, otherwise the building could not be completed. WREN resembled one of the military commanders of that age who directed campaigns, but whose swords were only signs of authority. The modern architect, on the contrary, must imitate the ancient leaders who had to use their own hands if they expected to be victorious. Every stone in his building should be familiar to him, for he has endeavoured to realise it on paper. WREN was deprived of the training which makes a hand with a pencil in it more expressive than the tongue. Two years before his death he prepared a list of his essays, but prior to 1661, when he received the

Photographed by Bolas &amp; Co.

THE CROSS OF ST. PAUL'S.

Let my path  
Lead to that younger Pile, whose sky-like dome  
Hath typified by reach of daring art  
Infinity's embrace; whose guardian crest,  
The silent Cross, among the stars shall spread  
As now, when She hath also seen her breast  
Filled with mementos, satiate with its part  
Of grateful England's overflowing Dead.

WORDSWORTH

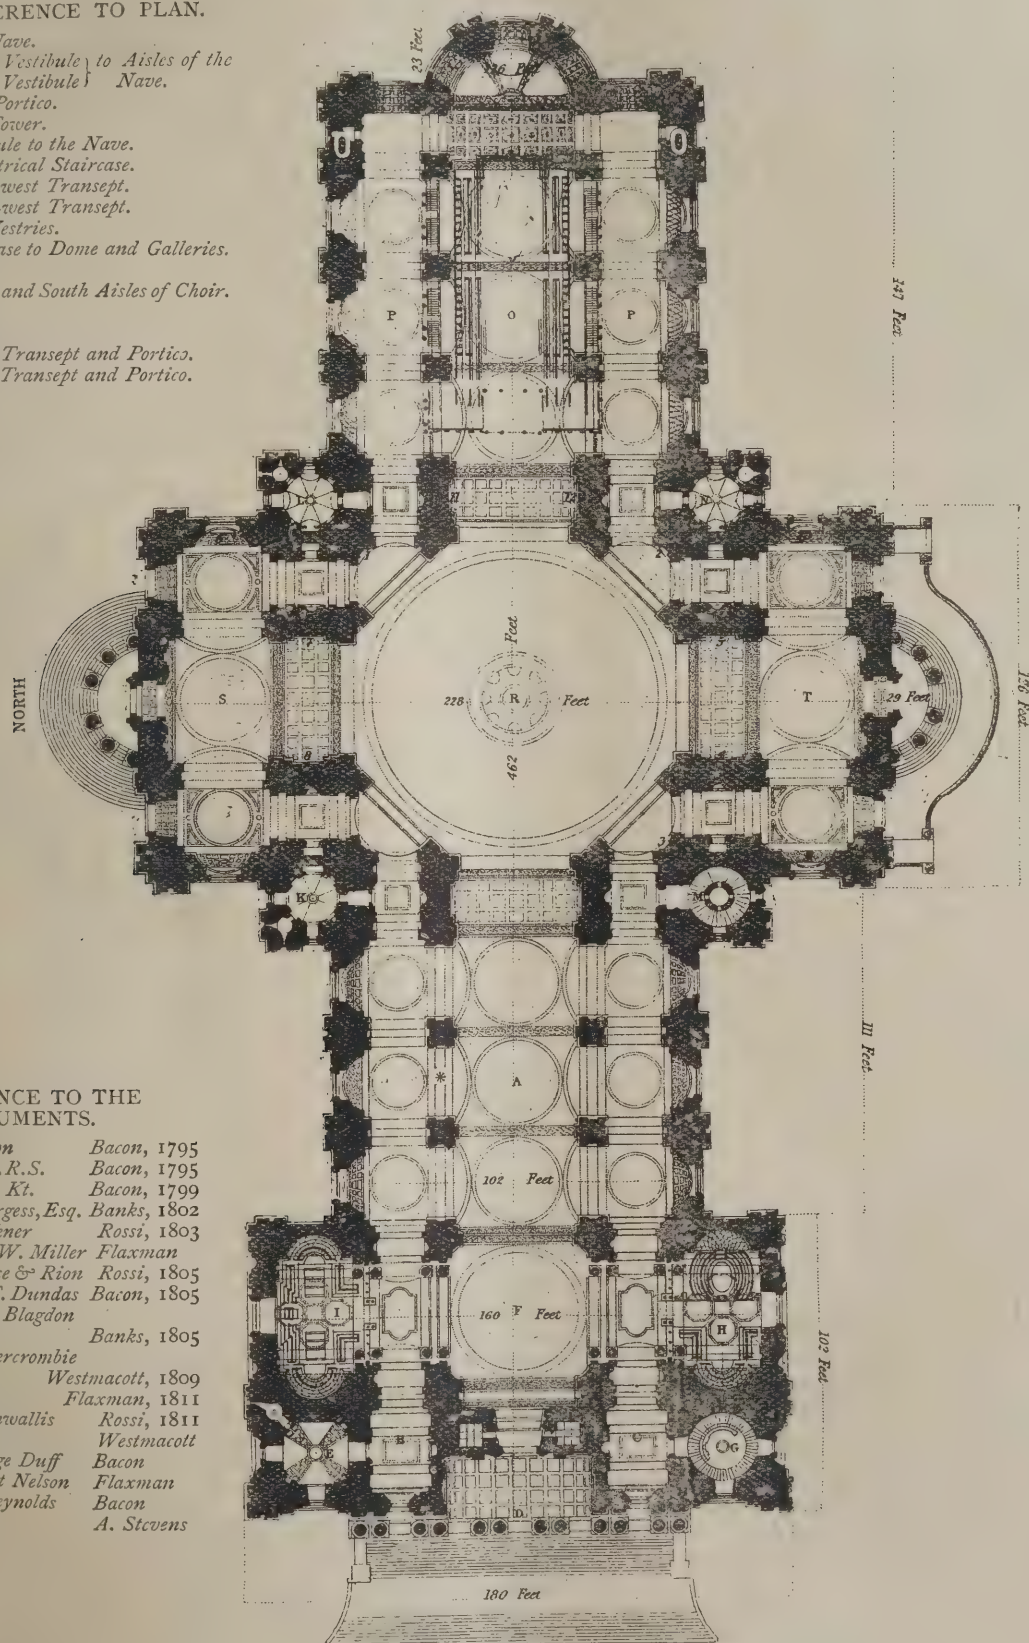

appointment of Deputy-Surveyor-General, we cannot trace one among them that required other illustrations than those of a geometrician. He was a man of science, occupied with mathematical, astronomical and microscopic investiga-

backyard before my eyes broke into roses and lilies." The Dean's poetic inspirations may have appeared a sort of eruption, but architecture does not come so easily, and is not a sign of disease.

tions. But building in those days was supposed to be an affair of science. Art was a sort of impromptu. WREN, says the poetic Dean MILMAN, "suddenly broke out as an architect," and he did not perceive his figurative language was as absurd as if he said, "A holly tree in the deanery

WREN could not say, with the late GEORGE STREET, that of the thousands of drawings required there was not one which did not present more or less of his handiwork. Nevertheless, he was the builder, the creator, of the cathedral. An architect has to deal with stubborn mate-

rials, but WREN could say they were flexible if compared with the obduracy of men who are indifferent to consequences so long as they obtain a momentary victory. WREN was as upright as any perpendicular line, and on that account, in an age partly feudal and partly corrupt, he made enemies. The proud Duke of SOMERSET treated him as a menial; the masons and hodmen, who were deprived by WREN of the luxury of cursing and swearing, looked on him as more a tyrant than the Grand Turk, and sought to ruin him by mutinies. So little confidence was placed in him by the Commissioners of St. Paul's they insisted on retaining half his allowance, as if he were likely to be negligent, and eventually an effort was made to deprive him in his old days of the money he had earned. As we have said, it is not possible to determine WREN's share in the production of the designs for St. Paul's, but we know enough of the contests in which he was engaged to make the building appear as a memorial of a brave and honest man, who was inspired by a sense of duty and believed he was aiding religion. He was near his end when he said, "If I glory, it is in the singular mercy of GOD, who has enabled me to begin and finish my great work so conformable to the ancient model." MICHEL ANGELO could not express himself with more sublime humbleness before Heaven and antiquity.

In ordinary cases an architect's difficulties begin with the preparation of the site. WREN was less fortunate, for there was many a struggle before he could arrange for a new St. Paul's. Two years after his appointment as Deputy-Surveyor he was ordered to prepare plans for the restoration of the old cathedral. He followed INIGO JONES in proposing that the additions should be in the style of the time—that is, Italian—and the lofty Gothic spire was to be superseded by a dome. The opposition of the clergy was not to be overcome, but WREN, relying on the power of CHARLES II., anticipated that his project would be realised. He therefore visited France in order to study the style, and it may be in order to engage assistants. It was at the period when BERNINI was receiving almost royal honours in Paris, although his plans for the Louvre were impracticable. WREN returned to London with "all France on paper." Before he could obtain a final decision on the restoration of St. Paul's the fire of 1666 left the building in ruin. He was eager to demolish the parts which remained, but unwillingly he submitted to the desire of a majority of the Cathedral Commissioners, and prepared plans for a restoration. It was not until 1668 that WREN's project for a new building was considered to be deserving of adoption. On July 20, after a council at which the king presided, he was directed to "take down the walls and clear the ground to the foundation in such manner as shall be judged sufficient to make room for a new choir, of a fair and decent fabric, near or upon the old foundations."

WREN employed powder as an agent in removing parts of the walls, but as one of the stones was impelled some distance and frightened a few women, it was decided to take a lesson from the ancients and employ a sort of battering ram. The following account of it appears in the "Parentalia":—"He took a strong mast of about 40 feet long, arming the bigger end with a great spike of iron fortified with bars along the mast and ferrels; this mast in two places was hung up by one ring with strong tackle, and so suspended level to a triangle prop, such as they weigh great guns with; thirty men, fifteen on a side, vibrated this machine to and again, and beat in one place against the wall the whole day. They believed it was to little purpose, not discerning any immediate effect. He bid them not despair, but proceed another day; on the second day the wall was perceived to tremble at the top, and in a few hours it fell."

The ground must have suggested that chaos was come again. Surveying instruments apparently could not be obtained, and from the size of the heaps of blackened stone it was impossible to lay out the lines of the foundations from a small plan. WREN was therefore compelled to erect a platform corresponding in area with the part to be excavated, and on it to represent a plan of the foundations of full size. Having determined the points, corresponding points were fixed by plummets amidst the hillocks underneath. WREN's skill as a mathematician in this part of the undertaking was invaluable. He must

have allowed himself more or less latitude in fixing the lines. There was then no approved plan of the new building, and WREN found it necessary to be prepared with a variety of projects for the cathedral. What was most urgent was the clearing of the ground. When that was accomplished the excavations began. As often happens, firm ground was found at a little depth. But in the part which was likely to support one of the piers of the dome a pit was revealed, from which the clay was taken by Roman potters and brickmakers. It extended from 40 to 50 feet beneath the soil, and was filled with potsherds. WREN then concluded that if he wished to have a secure foundation he must carry up the work from as great a depth, or, in other words, from a level corresponding with the bed of the Thames. When he was advised to employ piling he answered, "Piles may last for ever when always in water, but if they are driven into sand and kept between wet and dry they will rot. *I desire to build for eternity.*" WREN therefore opened pits or wells 18 feet square, which were excavated until a bed of sand and shells was reached, and afterwards filled with masonry or brickwork. He next sought for the best stone, and after inquiries decided on the adoption of Portland stone, which had been selected by INIGO JONES for the Corinthian portico which was added to Old St. Paul's.

WREN'S GREEK CROSS PLAN.

While the preliminary operations were advancing towards completion owing to WREN's foresight, the plan to be employed was still in abeyance. It was not until May 14, 1675, or nine years after the fire, that the Council were able to arrive at a decision. WREN, as we have said, was prepared with plans that could be adapted readily to meet the views of any party that gained supremacy, but he shrewdly concluded the choice would be either for a building according to the plan of a Greek cross, or one on the later Italian plan, as is the existing building. His own preference was for the former. WREN did not believe in processions, and did not care for a nave or aisles that were long drawn out. There was, he considered, a central point in an English church where a pulpit was placed, and the congregation should be enabled to approach it without difficulty. It is generally believed that the Duke of YORK, afterwards JAMES II., was the principal opponent of that design, for he was anxious to have a cathedral which would serve in case there was a return to the old ritual after he arrived at the throne. It is possible that JAMES as well as CHARLES were inspired by a different motive. In those days royalty was accompanied on occasions of State by a train of courtiers. They could not be massed in a crowd. Degrees of precedence had to be expressed, and a processional order was inevitable. Ordinary citizens could be allowed to hasten

to the best place for hearing a sermon, but it was not to be expected that a king of England would visit the cathedral of his capital with such expedition. In the old cathedrals the monarch and his court were enabled to approach their seats with becoming dignity. In the later churches of France and Italy there was also provision for ceremony, and, indeed, to royalty the Greek cross plan must have signified a retrenchment of those ceremonies which were identified with the kingly office. It was not to please the priests of a future and most uncertain time, but rather to gratify his own desire for display, that the Duke of YORK was inimical to WREN'S pet plan. The architect was moved to tears by the opposition, and it is to be regretted he was not allowed to have his way. The model which was prepared suggests a more excellent building than the present cathedral, and it must also be allowed that the number of royal processions through the nave has been too few to compensate for the sacrifice of so noble an architectural design as WREN had prepared. In the services the original plan has asserted its advantage, for it is under the dome and in the adjoining parts that large congregations are now to be found. Although WREN could not work at the new building with all his strength, yet, as MACAULAY says, "No man born on our side of the Alps has imitated with so much success the magnificence of the palace-like churches of Italy; even the superb LOUIS has left to posterity no work which can bear comparison with St. Paul's."

(To be continued.)

## METHODS OF CHARGING FOR ELECTRICITY.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

(Concluded from last week.)

NOW it is evident that if a consumer uses his lamps for any purpose at, say, midday, or at any time when the maximum load is not on, he is not demanding plant for himself, but is merely using (to the benefit of the company or corporation) that plant which the consumers at a time of maximum load have demanded, but which is not in use in the daytime. Thus it is clear that he should not have to pay for this. Under either of these systems, however, he does.

If all the consumers used their light at the same time, *i.e.* if the sum of the maximum demands read on the meters were equal to the highest load at the station, the maximum demand system at Hastings would be perfectly just, and it may be taken that in proportion as the sum of the maximum demands read on the meters exceeds that noted at the station, the systems discussed become unjust. Mr. HORDERN, assistant manager of the Westminster Electric Supply Corporation, has shown that for his district the sum of the maximum demands would exceed the maximum load on the stations to such an extent as to render either of these systems ridiculously unjust; in fact, more so than the simple one of charging a fixed sum per unit.

The theoretically just system referred to would not be really just, as a consumer who, as a rule, used his maximum demand at a convenient time—*i.e.* when very few lights were on—might possibly switch on his lights at the moment of heaviest load during the year, and would consequently have to pay his share of the standing charges for the whole year; or again, the worst consumer might omit to turn on his lights, and would escape without any standing charges, and only pay the  $1\frac{1}{4}$ d. per unit. It is obvious that any of these systems are unjust in one way or another, and, on the whole, it may be said that the Hastings system is the most equitable of this class yet devised.

As before mentioned, this article is from the consumer's point of view, and so the effect of these systems on the central station is of little importance, except so far as they concern the consumer. It has been proved by experience that the Hastings and Brighton systems have, wherever used, greatly improved the load-factor, *i.e.* increased the time of heavy load on the station. The effect of those systems is to cheapen the use of electricity for all purposes where the light is required for long hours, and so encourage the paying consumer. The result is that the bad consumer is dissatisfied, and the good one encouraged greatly—the

very best arrangement possible, for the bad consumer not only is a loss to the supply company, but to his fellow consumers, as the loss caused by him has to be made up by his neighbours if the undertaking is to pay. Everybody would be better off if consumers who do not use their maximum demand at times of full load for  $1\frac{1}{2}$  hours a day were disconnected from the mains. The results, then, of the Hastings and Brighton systems are that, because the load-factor is improved, the economy of the station is increased and the capital used to better advantage; the price of electricity is far less to everyone than with a bad load-factor.

It must not be imagined that the systems described are the only ones which achieve the above object. GIBBERT KAPP, at about the same time as HOPKINSON, developed the subject on different lines. He did not go into the question in the same way, but arrived at a result which is, on the whole, more simple and more to the point. It was seen that the load on an electric-light station was practically of only three or four hours' duration. Therefore, from a question of *policy* and not of *justice*, Mr. KAPP and others said, "We will charge half-price for power, and in some cases light, taken between, say, 8 P.M. and dusk the next day. This will encourage people to use electric motors and other apparatus for commercial purposes, and so enable us to keep the machinery running more fully loaded and to increase our profits." In fact, it was the principle on which the seaside hotel proprietor works. The proprietor does not go into the questions of perfect justice, but the price of his commodity is regulated by expediency, or, in other words, the law of supply and demand; or, in still stronger words, he extorts as much as he can persuade people to pay. It is difficult to persuade consumers to turn on their lamps when they do not want them, but it is easy to encourage those good customers who want power or light when other people do not, and so increase the average quality of the consumer, or the load-factor, and incidentally the profits. The chief concern, however, from the consumer's point of view, is that of paying a just amount for services rendered; and as will be seen from a study of the results of the two methods, justice and expediency come to the same thing, *viz.* that the man who uses his light or power in the daytime or for many hours gets a reduction.

There are many arrangements existent by which the meter is made to register less in the daytime. One arrangement, that used to some extent in St. Pancras, consists in having two meters, one of which indicates at 6d. per unit and the other at 3d. The current consumed on the premises is passed through the 3d. meter in the day and the 6d. meter in the evening; the change over is, in some cases, done by a clock contact, and in others by separate thin meter wires going from the station, which actuate a switch. In other cases, one meter is used and shunted by a similar clock service, so that only a portion of the current passes through it in the time of light load. The system in use at Norwich is as follows:—Special meter wires are used, which are connected to an apparatus by which the coils of an ammeter are shunted. The current is switched on these wires automatically at intervals, thus causing the ammeter to return to zero. When the current is switched off the meter wires, the ammeter again moves an amount proportional to the current, and in doing so moves by means of a pawl a wheel connected to the counter and dials. The result is that the dials are moved forward periodically by an amount proportional to the current, and thus they show the units delivered. The current is switched on twice as often after an hour before sunset every evening till the load goes off the station, and the meter thus registers twice as fast in the evening as in the day.

At Bristol the Kapp system is, or was, used, and the meter caused to read slower in the day by resistance being switched into the shunt circuit.

There is no doubt that if the difficulties of clocks, &c., can be surmounted at a reasonable cost and the working made reliable, that these methods are far more satisfactory than the maximum demand systems, and they really are the same thing only more just, because at the time of maximum demand the price charged is much higher than at others, and this tallies with the results of the costs of working, the standing charges being to a great extent caused by this maximum demand.

There are yet several other systems of charging, one introduced by Mr. PINK, late burgh engineer at Ayr. This consisted in allowing discounts on business premises which varied with the time of closing. Those which closed early were allowed no, or very little, discount, and those closing later were allowed a larger one on their bills. Such a system is, of course, out of the question in a residential district or in a large town, owing to the difficulties of insuring that the declared time of closing is adhered to and of determining the time of closing for private houses.

A system somewhat similar to the above has been devised by the author for Queenstown (co. Cork), where there are many reasons which make a contract system desirable. It has been arranged that the contract price is such that the cost per unit (calculated on the basis of a 30-watt lamp burning from dusk till the declared closing time) is less as the time of burning increases. The system provides that the cost per candle-power lamp and per unit is as follows:—

Time of Closing.	Hours per Annum.	Contract Price.	Equivalent Price per Unit.
6 P.M. . . . .	226	8s. per annum	14.2d.
7 " " " " . . .	430	10s. " "	9.3d.
8 " " " " . . .	730	12s. " "	6.55d.
9 " " " " . . .	1,090	14s. " "	5.15d.
10 " " " " . . .	1,455	16s. " "	4.4d.
11 " " " " . . .	1,820	18s. " "	3.95d.
12 " " " " . . .	2,185	20s. " "	3.6d.

All houses which light at dusk and close before 6 P.M. will be charged as if they closed at 6 P.M.

In any case where difficulties arise as to determining time of closing, or where a day load is required, or where the consumer has broken his part of the contract persistently, a meter will be fixed, and a two-price system will be used, as at St. Pancras, 7d. in the evening and 3½d. for the rest of the time.

For the sake of clearness the basis on which the various systems are worked out are restated:—

Brighton System.—7d. per unit first hour, 1½d. per unit after.

Manchester System.—1s. 4½d. per 8 candle-power lamp connected per quarter and 1½d. per unit sold.

Hastings System.—1s. per 8 candle-power lamp demanded in each quarter and 3d. per unit after.

Two Price (Norwich).—7d. per unit between dusk and 8 P.M. (7 P.M. Sundays), and 3½d. per unit all the rest of time.

Discount on Closing Time.—Shops closing at 8 P.M. 5 per cent. discount; 9 P.M. 19.5 per cent. discount; 10 P.M. 22.5 per cent. discount; 11 P.M. 35 per cent. discount of the bill (7d. per unit).

Contract Discounts.—As above described.

To conclude, it has been shown that a uniform charge per unit is not fair when applied to central-station supply, and that a system should be devised which would vary the charge in some manner similar to the variation in the cost of supplying the units sold, and, in fact, charge on the constant-profit system, not constant price. The consumer who uses his lights many hours a day is more profitable than those who do not. At Brighton it costs two and a half times as much per unit to supply a consumer who uses his lights one hour a day on an average as it does to supply one who uses his lights on the average three hours a day. The Hastings system is the more equitable of the maximum-demand systems, and on the whole the two-price system is the most satisfactory in the author's opinion.

My thanks are due to Mr. FENNELL for the willing assistance given in the preparation of this article.

#### A ROYAL PAGEANT IN 1558.

THE following account, somewhat modernised in language, of "The Passage of our Most Dread Sovereign Ladye Queen Elizabeth through the Citye of London to Westminster the day before her Coronation, Anno 1558," may not be without interest at the present time, when the City is about to be the scene of another royal progress:—

"On Thursday, the 12th of January, 1558-59, Her Majesty removed by water from her palace at Westminster to the Tower, attended by the city barges, trimmed with targets and banners of their mysteries.

"On Saturday the 14th she took her passage through London, leaving the Tower at two o'clock.

"Near Fenchurch Street was erected a scaffold, richly furnished, whereon stood a 'noise,' or band of instruments, and a child in costly apparel, who welcomed the Queen with a poetical address. At the upper end of Gracechurch Church, before the sign of the Eagle, the city had erected a gorgeous and sumptuous arch, occupying the whole width of the street. It was battlemented, and had three portals, over the centre of which were raised three platforms, rising in three degrees or steps. Upon the lowest, in one royal seat, were placed children representing King Henry VII. and Elizabeth, his wife; the former surrounded with a red rose and the latter with a white one, but having their hands united, each with a ring of matrimony to be perceived on the finger. Out of these two roses sprung two branches, gathering into one, which was directed to the second stage, where sat King Henry VIII., with Queen Anne by his side, from whom again grew a branch to the utmost stage, where Queen Elizabeth herself was personified. The Queen here, as throughout, made every effort to appreciate the exertions made in her honour. She even desired her chariot, which passed too far, to return, and personally required to have the matter open to her. When this was done, she thanked the city, praised the beauty of the work, and promised that she would do her whole endeavour for the constant preservation of concord, as the pageant did import.

"The second pageant, at the nether end of Cornhill, was inscribed 'The seate of worthe governance.' This, like the former, was a gateway, with three open arches; and over the centre was a child, representing the Queen, placed in a seat which seemed to have no other support but that of four personages, representing the virtues, Pure Religion, Love of Subjects, Wisdom and Justice, each of which trod under foot their contrary vices—Superstition and Ignorance, Rebellion and Insolency, Folly and Vainglory, Adulation and Bribery. Above all were the royal arms.

"The Great Conduit in Cheap was beautiful with pictures and sentences.

"At Soper Lane End was another pageant of three open gates, above the centre of which, on three stages, sat eight children. The eight beatitudes applied to our Sovereign Lady, Queen Elizabeth.

"The standard in Cheap was dressed, and near it was posted a noise of trumpets.

"The Queen had scarcely passed the cross when she espied the pageant erected at the little Conduit, and immediately required to know what it might signify. It was told her grace that there was placed Time. 'Time,' quoth she, 'and Time hath brought me hither.' The attendants then proceeded to describe the whole matter, but at the beginning, where she understood that the Bible in English was delivered to her by Truth, she thanked the city for that gift, and saying that she would oftentimes read over that book, commanded Sir John Perrot, one of the knights who sustained her canopy, to go on before and receive the book. Being told, however, that it was to be delivered down by a silken lace, she desired him to stop, and so passed forward until she arrived at the spot where the aldermen stood. There the Recorder presented the Queen with a thousand marks of gold, contained in a purse of crimson satin richly wrought with gold and accompanied by a suitable address. Her Majesty took the purse with both hands and replied so 'marvellous pithilie' as to excite the admiration of all the bystanders.

"I thank my lord mayor, his brethren and you all. And whereas your request is that I should continue your good lady and queen, be ye assured that I will be as good unto you as ever queen was to her people. No will in me shall lack, neither do I trust shall there lack any power. And persuade yourselves that for the safety and quietness of you all I will not spare, if need be, to spend my blood. God thank you all.'

"Which answer," says the record, "of so noble-hearted a princess, if it moved an extraordinary shout and rejoicing, it is not to be marvelled at, since both the heartiness thereof was wonderful and the words so jointy knit.

"We now arrive at the pageant where the Bible was presented. It was on a square erection, standing directly before the little Conduit with battlements, and on it were represented two hills or mountains, that on the north cragged, barren and stony, with a withered tree, under which sat one in a homely apparel and in a mourning attire, with a tablet over his head, inscribed with his name in Latin and English, '*Ruinosa Republica*'—'A decayed Commonwealth.' The other hill was fair, fresh and beautiful, the ground thereof full of flowers, and having a flourishing tree, under which stood upright, '*Republica bene instituta*'—'A flourishing commonwealth.' Each tree was also hung with appropriate sentences. Between the hills was a hollow place or cave, out of which, a little before the Queen's coming, issued Time, an old man with wings and a scythe in his hand, leading a personage of less stature than himself, clad in white silk, whose name set over head was '*Temporis filia*'—'The Daughter of Time,' and on her breast '*Veritas*'—'Truth.' In her hand she held a book inscribed '*Verbum Veritatis*'—'The Word of Truth.' A child in front

delivered the poetical explanations, during which Truth let down the Bible from the hill, and Sir John Perrot, receiving it, kissed it, held it up with both hands and laid it upon her breast.

"In St. Paul's Churchyard a child of the school (Christ's Hospital) pronounced a Latin oration, and then delivered to Her Majesty a copy fairly written on paper, having first kissed it; it was received 'most gently.'

"Ludgate was finely trimmed and furnished with music. At the Conduit at Fleet Street was the fifth and last pageant. It was a stage embattled with four towers. A throne raised on steps was overshadowed by a large tree, having leaves and the fruit of the date—a palm tree. In the throne sat a queen in Parliamentary robes, named in a tablet over her head, 'Deborah, the judge and restorer of the house of Israel.' A child was ready to speak, and in order that she might better hear him, the Queen required silence, and commanded her chariot to be moved nearer.

"At St. Dunstan's Church the children of Christ's Hospital stood with their governors, and one of them delivered a Latin oration.

"The final exhibition was at Temple Bar, which was 'finely dressed,' with the two giants, Gotmagot the Albion, and Conneus the Briton, who held between them a poetical recapitulation of the pageantries both in Latin and English. On the south side were singing children, one of whom, richly attired as a poet, gave the Queen farewell in the name of the whole city."

### THE SIDDONS MEMORIAL.

ON Monday the statue of Sarah Siddons, the tragic actress, was unveiled on Paddington Green by Sir Henry Irving. The figure was inspired by Reynolds's great painting of *Mrs. Siddons as the Tragic Muse*, belonging to the Duke of Westminster, of which we published an illustration last year, but it is no mechanical copy. The sculptor was M. Chavalliaud, who worked under Messrs. Farmer & Brindley, of Westminster.

Sir Henry Irving, before unveiling the statue, spoke as follows:—It is a great pride to me to unveil this statue and to congratulate the inhabitants of Paddington on the possession of so admirable a memorial of a famous Englishwoman. London is rich in statues, chiefly of people whom nature did not expressly design to be immortalised in that particular way. Few men or women look well in marble or bronze, but to-day you see one of the ideal models of the sculptor's art—a great actress whose personal majesty is eloquent even in the silence of stone. It was said of Sarah Siddons by Hazlitt that "she was not less than a goddess or a prophetess inspired by the gods. Power was seated on her brow, passion radiated from her breast as from a shrine; she was tragedy personified." I think you can catch the spirit of that panegyric from the impressive figure, so admirably designed and executed by M. Chavalliaud, which is set up in your midst to-day. By the acclamation of her contemporaries Mrs. Siddons was hailed as the incarnation of the sublime in the expression of dramatic passion. I have lately read that this ideal of the sublime is a mere supposition, belonging to a world of art and emotion which has definitely passed away. It will pass away when the creations of Shakespeare become obsolete, when the highest poetry ceases to influence the soul of mankind—conditions which make the fulfilment of such a prophecy unspeakably remote. Methods of execution in art may vary from age to age; but in this monument you have a standard of conception which has made the name of Siddons imperishable. To some characters in Shakespeare, such as Lady Macbeth and Volumnia, she gave a tradition which has not been effaced. Moreover, in honouring her memory you are paying a lasting tribute to a quality which is the perpetual stimulus to ambition in every walk of life. To every young man who looks upon this statue I would say, "This is not only the image of a great actress, it is the image of indomitable energy and perseverance. When she came to London first she was a conspicuous failure. She went back to the hard school of the provincial theatre and matured her powers by unflagging industry. This is no memorial of casual and irresponsible genius, but a triumphant witness to the merits of those comrades-in-arms of all true endeavour—application and a stout heart." Another noteworthy point of this monument is that it is the first statue of a player that has been erected in London. I am not suggesting this as a precedent for the further embellishment of advantageous sites, but in itself—and one cannot help dwelling upon it—it is a considerable portent. There are statues of Shakespeare, and the dramatic profession does not forget that Shakespeare was an actor, and that but for his connection with the stage it is improbable that he would have enriched our dramatic literature. However, if it is for Shakespeare the poet, not for Shakespeare the actor, that we have raised trophies for triumphal show, we have before us to-day a striking proof of that public spirit which has sacrificed an ancient social

prejudice in homage to a great actress, which needs no better evidence than the generous gift of the site by the Vestry of Paddington, together with their handsome provision of the base of the statue. This is a monument of enlightened tolerance which would have surprised most people in Sarah Siddons's lifetime. It shows, moreover, that the work and influence of the actor are not quite ephemeral. Mrs. Siddons died a very few years before our gracious Sovereign came to the throne, and amongst the evidences of that spread of ideas which has distinguished Her Majesty's long and glorious reign, I think we may claim this permanent recognition of the genius of a woman who shed lustre upon her generation and stood pre-eminent amongst the race of great English actors.

When the cheers following upon Sir Henry's concluding words had died away he turned to the statue in front of which he had stood whilst addressing the gathering, and, pulling a cord attached to the striped cloth which covered the monument, revealed to the gaze of the onlookers M. Chavalliaud's finely executed figure of the illustrious actress. The statue, which stands on a pedestal of Portland stone, has been wrought of gleaming white Carrara marble, and represents Mrs. Siddons reclining in a characteristic and dignified attitude on a chair of Grecian shape, her right hand clasping a dagger and her left supporting her chin. By all present the work was acclaimed a striking embodiment, and worthy to serve as a permanent memorial of the player of whom, in dedicating her features to posterity, Sir Joshua Reynolds remarked that by inscribing his name on the hem of her garment his fame would be preserved for all time.

The Dean of Hereford, in moving a resolution of thanks to the donors and subscribers, remarked that he was closely related by marriage to the illustrious Kemble family, his wife's mother being Fanny Kemble, who was niece of Mrs. Siddons. It was from Hereford that the Kembles sprang, and well might that city be proud of having produced such a family, and also such a man as David Garrick. After alluding to the failure of Mrs. Siddons and her ultimate success, the Dean said that the stage might be used for great moral good, as it might be degraded to evil. Therefore, they were thankful that the Kembles in the past, and Sir Henry Irving in the present, had laboured to make the stage not a mere source of amusement, but a source of intellectual education.

### EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual excursion to Linlithgow will be made to-morrow, Saturday, June 19, when the party will visit the palace, in which building is work of the fifteenth, sixteenth and seventeenth centuries, and probably it is the finest example of Domestic architecture remaining in Scotland. It is built in the form of a square with a central courtyard. All the apartments communicate with each other and with various staircase towers. On the south side the entrance to the palace and the royal chapel are situated. On the east side is the great hall, a most magnificent structure, and also another entrance of great richness of decoration. The west side is occupied with what were probably family apartments, and on the north side there are various banqueting halls, an oratory, kitchens, &c. St. Michael's Church adjoins the palace, and consists of a nave and choir, with north and south aisles, eight bays in length, a western tower and an eastern apse. The north and south chapels may be regarded as transepts. The fine southern porch has a priest's room over it lighted by a beautiful oriel. After luncheon the members of the Association will inspect Bonhard House, situated about two miles north from Linlithgow, a building of the L plan, with a staircase turret in the re-entering angle. Some of the rooms have ornamental ceilings, with panelled walls and handsome fireplaces. The house was built by the Cornwalls, a well-known Linlithgow family, and their arms, with the date 1591, are beautifully cut on a dove-cote at Bonhard. They will also view Kinneil House, an ancient possession of the Hamiltons, consisting of an oblong keep, 56 feet 6 inches by 31 feet 6 inches, to which wings have been added, and also a block of buildings to the north-east, which may at one time have been a separate house. The keep walls are 6 feet thick and the ground floor is vaulted. Frequent alterations render it difficult to assign the date of this structure. The attached building was originally L-shaped and combined with the keep into one building in the reign of Charles II.

The Tapestry Map of Warwickshire and adjacent counties, dated 1588, belonging to the York Museum, which was exhibited at the Royal Geographical Society some time ago, has been carefully cleaned and repaired, and will be on view at the School of Needlework, 17 Sloane Street, from June 24 to July 10.

## NOTES AND COMMENTS.

IRELAND is rich in examples of prehistoric monuments. According to Mr. BORLASE there are 234 dolmens in the province of Munster, 248 in Connaught, 227 in Ulster and 71 in Leinster, or in all 780. There are also 50 chambered tumuli and 68 monuments of other varieties. No less than 40 of the chambered tumuli are in Leinster, the rest of the island containing only 10. A capstone or table stone of a dolmen in Kermanstown, Carlow, is calculated to weigh 100 tons, while one at Howth, near Dublin, weighs 70 tons. Mr. BORLASE offers the following explanation of the means of transit adopted by the men who raised the memorials:—"The very existence of these megalithic structures appears to me to be an indication—if, indeed, such were needed to demonstrate the fact—that Ireland was once a well-timbered country. It must have been by the power of mighty leverage that these stones were lifted into place, and such leverage could only be obtained with felled timber. The trees once felled, with the aid of chisels of stone or bronze, and the application of fire, and points for purchase being obtained beneath the rock, four or five trunks heavily weighted at the opposite extremity could, with the aid of the united action of a fairly large body of men, be brought to bear at once in lifting the stone little by little. As the work of elevation went on, stones would be inserted to prevent the mass from falling back. The pillar-stones destined to support it would then be fixed on the ground beneath its edge, the small trigging stones gradually removed, and the mass allowed to sink on to the summits of the uprights." The builders, according to Mr. BORLASE, were the predecessors of the Celtic tribes. They were cannibals, and in that propensity resembled, it is believed, the builders of the Egyptian pyramids.

THE advantage of presenting a museum to a town is suggested by the experience of the people of Kilmarnock. One of the townsfolk agreed to erect a building on the site of the temporary museum in Elmbank at a cost of 8,000/. That gift made an almost unique collection of corals belonging to Mr. JAMES THOMSON, F.G.S., available for the town. Dr. HUNTER-SELKIRK has now presented the contents of his museum at Braidwood. Kilmarnock has consequently acquired about 30,000 old coins, 117 old bibles, illuminated manuscripts, numerous relics of the Covenanters, rare specimens of Wedgwood ware, old watches, snuff-boxes, pottery, &c. The geological specimens are illustrative of local peculiarities, and will be invaluable to students of the science. In most places the filling up of a museum is a slow operation, but at Kilmarnock the cases can be filled as soon as they are completed. It may also be assumed that many other collectors will be disposed to enrich the building.

In Kent there will soon be a commemoration of the thirteenth centenary of the landing of St. AUGUSTINE at Ebbs Fleet. In Iona another ecclesiastical event of the same date is now being celebrated. St. COLUMBA having accomplished his task passed away as the Roman monk arrived. There must have been a wide difference in the appreciation of architecture between the two. St. AUGUSTINE was familiar with the great buildings of antiquity, and no doubt endeavoured to secure churches that would be worthy of their purpose according to his standard. St. COLUMBA could hardly have known of a building of stone and mortar. His first foundation was a cave-chapel at Loch Coalisport. Then, having obtained permission from the Picts to settle in Iona, he founded a monastery. Messrs. MACGIBBON and ROSS, in their "Ecclesiastical Architecture of Scotland," describe it as in the ordinary style adopted in Ireland. According to ADAMNAN, the biographer of the saint, the buildings were constructed of wattles and turf, and the roofs covered with thatch. There was a special cell for the abbot, a larger hut for a refectory and another for strangers; the whole was enclosed with a high wall or rampart. About a century afterwards, when the monastery had to be improved, oak boards were used instead of wattles, and the roof was covered with thatch. The ceremonies of commemoration were held in the ruins of the church of St. Mary, which was the cathedral of Iona, an early thirteenth-century building, the

chancel and one of the side aisles having been roofed for the occasion. The use of the building was also allowed by the Duke of ARGYLL to the Roman Catholics for their services on the occasion. According to Dr. STORY, St. COLUMBA was "the founder of the Scottish nation, for had the Dalriadan kingdom fallen into unworthy hands at the time when COLUMBA named the energetic and able AIDAN as its king, and had its delivery from Irish vassalage not been achieved through his persuasion, one or other of two things would have happened, either of them fatal to Scottish independence and the development of a pacific nationality in which Pict, Scot, Briton and Saxon should form harmonious elements—Scotland still feudatory to Ireland would have become a mere appendage to that island, or, divided between hostile tribes of Picts and Scots, it would have fallen a prey to the Saxon aggressors from the east and south."

WE mentioned lately that the Médaille d'honneur for architecture in this year's Salon was not awarded because the chairman refused to count the votes which were given for M. MARCEL, the favourite, as a member of a firm of architects. The voters protested and the question was submitted to the adjudication of the committee. The voting on the former occasion was annulled. There was a new attempt and, as was desired, M. MARCEL was successful and accordingly was awarded the coveted distinction.

THE subscriptions to the monument of PASTEUR have reached 297,000 frs., or nearly 12,000/. But the money has come from all parts of Europe as well as from France, and the general recognition of PASTEUR's services to humanity is as creditable to his memory as any memorial in stone. It was the intention of the committee to have entrusted the work to M. PAUL DUBOIS, but that sculptor was afraid the task would interfere with his duties as director of the Ecole des Beaux-Arts, and declined to accept the commission. At his request it was confided to M. FALGUIÈRE.

THE gigantic trees of California have often been described, and one variety is made the subject of remarks by the British Consul-General in San Francisco in his last report. Redwood is the *Sequoia sempervirens*, the great tree of the coast belt of California. It attains a height of 250 feet or more, and, it is said, a girth of 60 feet. The Consul-General has measured some trees 45 feet in circumference between 4 feet and 5 feet from the ground, but these were not in the finest groves. The wood is said to stand any climate, from the dry heat of Australia or the interior of California to the dampest place, without being affected, after it has been thoroughly seasoned. The chief objection to its use is the difficulty of seasoning it. A board 6 inches thick will not thoroughly season in the warmest part of California under about two or two and a half years. This, of course, adds to the cost. Much of the wood is adapted for internal use and decorative purposes, such as doors, panelling of rooms and ceilings, dadoes, mantelpieces and over-mantels, &c., and once properly seasoned it never shrinks or cracks. Another advantage is that boards of great width can be obtained entirely free from knots. In colour the wood ranges from light to dark reddish brown. The varieties of graining are great. Some, especially the "curly" and the "burl," are very beautiful. The "curly" has a wavy pattern. The "burl," in its markings, is something like Thuya wood, but with larger markings, English oak "burr," and the finest knot walnut. This wood, however, except the "burl," is soft and liable to be marked by blows. When properly prepared it takes polish and varnish well. Certain articles of furniture, such as tables, are made from the "burl." The timber has been of late shipped to the United Kingdom, the annual shipment from San Francisco being about 7,000,000 feet or 8,000,000 feet. But much of what has been sent to England has been of a very inferior quality.

## THE ARCHITECTURAL SCHOOL OF THE BERLIN TECHNICAL COLLEGE.\*

WHEN I handed in the title of this paper, I was under the impression that the time available for reading it would have been the conventional one hour generally given to a lecture, and I had intended making an attempt to describe the chief feature of a well-known German technical college in all its departments. As it has been found necessary, however, to reduce the time available for each paper to twenty minutes, I am afraid that I shall have to confine my remarks to one of the sections of the institution with which I am to deal.

This institution is the Royal Technical College at Berlin, which, to my mind, is the leading establishment of its kind to be found in the German Empire, or, for the matter of that, in German-speaking countries, Austria included; and the section to which I shall devote my remarks more especially will be the architectural school or division of that institution. As an architect who has studied there, and has enjoyed the facilities of this special division, it will be easily understood that I should give preference to the department of which I have had considerable personal experience.

In the first place I would give a brief outline of the origin of this institution. The Berlin Technical College, as it now stands, has been in existence for only thirteen years, for it is since 1884 that it has occupied the premises it now holds. The scheme of organisation on which the establishment was based dates however from 1879, the intervening period being utilised chiefly for the preparation of the necessary buildings, which were designed and executed on a lavish scale. The present nature of the institution has grown out of an amalgamation of the old Architectural Academy at Berlin with the Engineering Academy of the same city, which previously had separate existences. Both had passed through similar phases of development, both having been started in a very modest way during the early years of the present century. These establishments were organised under the Prussian Government, and both were owned and practically managed as the property of the Prussian people. The new institution is also essentially a Prussian one, on which the Government of that country spends annually a considerable sum of money, and this point as to ownership of the original and, subsequently, of the new establishments, is an important feature to be remembered.

The old Architectural Academy to which I have just referred, though only in working in the opening days of the present century, officially dates from April 8, 1799, when a charter for a new "Bauschule," literally "Building School," or better school of building construction, was signed by the then reigning king, Frederick William III. Its organisation was primarily intended for the education of architects and surveyors who proposed entering Government service. The first curriculum of this early period included no less than twenty-three subjects, and though the qualifications for entry to the classes almost solely consisted in the possession of a good character and elementary education, the scope of the instruction was by no means limited. I should, perhaps, add that this institution was one of the first of its kind on the Continent. The old "Building School" very soon became popular and consequently its development was rapid; so much so indeed, that greater restrictions had to be placed on those wishing to become students. A few years later we hear that one year's practical experience in an architect's or surveyor's office was a primary condition for attendance at these classes. In 1801 no less than fifty pupils attended the schools and in 1805 the number had risen to seventy. Here I would particularly emphasise the fact that the establishment embodied only the requirements indicated by its title; it was a building school, pure and simple, not an architectural school in the modern sense. The classes were essentially of a practical nature. Architecture as an art, and design from an artist's point of view, were subjects dealt with by the Prussian Royal Academy of Art, which had then, as it has now, its architectural studio, and to which members of the "Bauschule" might belong. It was not until the year 1828, when Professor Stier was one of the leading masters of the old establishment, that the art side of an architectural education received the attention that it had long merited from the executive, and soon after, in 1835, more suitable accommodation for the development of this side was found in an extensive block especially erected by Schinkel. In 1849 the building school underwent reorganisation and became a bona-fide architectural academy, managed on university lines, and with all the freedom traditionally associated with German university life; and this not only refers to the organisation of the establishment as such, but also, on the one hand, to the spirit with which the masters treated students, and on the other, to the manner in which the students applied themselves to their studies. The organisation of 1849 practically remained unchanged until the great amalgamation of

1879 already alluded to. Throughout this period the courses were followed by an examination which entitled the successful candidate to certain claims for Government employment, and gave him the title of a Government architect, even if he did not choose to avail himself of a public office, but to practise privately as an architect or surveyor.

It would lead me too far were I to touch in a similar manner on the interesting development of the Engineering Academy, and hence I shall only note that in 1821 it was first known under the title of the Berlin Technical School. Its development was, as I have said, not unlike that of the Architectural Academy, both as regards classes, conditions of entry and so on, while in 1850 it was similarly reorganised on university lines, and from that date became an engineering academy proper. Mechanical and mining engineering, naval architecture and chemistry were comprised in its programme, and each of these sections was, to a certain extent, regarded as a separate department of the establishment.

The amalgamation of these two academies took place, as stated, in 1879, and resulted in the establishment of the Royal Technical College, which in every way possesses a university status, and is in no way to be compared to what we term a "technical college" in this country. In order that the College may offer the best opportunities for the most efficient education the executive retains the leading men of the time for its professorial chairs. The social and educational status of the student is high, for every candidate is expected to have enjoyed a superior education at a first-class school. From a German point of view, the expense of sending a youth to this college is by no means a small matter, though it may seem slight in comparison with English university fees. The whole time of the student has to be given up to his college work, a full course of instruction occupying four years or perhaps longer. The Royal Technical College has its five distinct branches or, if I may apply the academic term, faculties, *i.e.* (1) architecture; (2) civil engineering; (3) mechanical engineering; (4) mining engineering, chemistry and mineralogy; (5) general technical science. Each division has its distinct head, who is generally a *savant* of considerable experience elected from among the body of professors of the section in question, and the chancellor, vice-chancellor and general council of the establishment are elected on similar lines, subject to the approval of the Government and the sanction of the sovereign. The professorships are in the gift of the King; the tutorships are granted by the executive. The students rank with university students, and their characteristics and pastimes are almost identical. The Royal Technical College is housed in what is doubtless the finest building ever devoted to an educational establishment of this description, in fact, it is quite a palace having considerable architectural pretensions. It cannot be too much impressed on those who have witnessed technical classes carried on in almost squalid surroundings, how important it is that we should give to technical students a home which in every way embodies the achievements of this age of progress in technical science, and does credit to the period of architecture to which it belongs. I should much like to have described the beautiful building and its practical equipment, which might well serve as a model to the world, though its conception is perhaps almost too elaborate and too costly from an economic point of view. I must, however, content myself with saying that its dimensions are approximately 700 feet by 300; that it has five courts, of which the central one is covered in, and that it has four storeys, all of considerable height. Its lecture-rooms are spacious and numerous, and its class-rooms and studios thoroughly serviceable and well lighted. The number of students for which it was intended was 2,000, and to-day, although there are 2,913 on the books, it still admirably fulfils its purpose, though the popularity which its educational facilities have won for it will, no doubt, soon compel a considerable extension being made. Of these 2,913 students I should here, perhaps, at once add that there are only 366 architectural students: fully matriculated, with 221 non-matriculated, making in all 587; whilst the mechanical engineers number together nearly 1,300. I should also, perhaps, add that there are a considerable number of foreigners among the students, Russia, for instance, regularly sending a large contingent.

But, turning now to the courses available for students of the architectural section, I ought first to say that besides the subjects taught in the architectural division proper, much that is valuable is to be learned from the civil engineers' department, in the general technical classes, &c., and special facilities are afforded to the architectural student for attending suitable lectures in other sections. The architectural division has eight ordinary and twelve extraordinary professors, and fifteen tutors headed, as I have said before, by a divisional chief elected from among the professors. The courses available include a large number of different lectures on various periods of architectural and art history. Further, elementary and advanced drawing, freehand, perspective, geometrical and architectural draughtsmanship, water-colour work and modelling. Then again, there

\* A paper read by Mr. Edwin O. Sachs, at the Congress of Technical Education.

are classes for the general planning of private dwellings and public buildings of all descriptions, for design in various specific styles and for divers purposes, the designing of ornament, of furniture, of lead-glazing, metal-work, &c. In addition to these, there are exhaustive lectures on the evolution of particular features in design, such as that of ornament; while among the more practical subjects every form of construction is taught, from the simplest brickwork to the most complicated iron roofing. The characteristics of different materials are also important subjects dealt with, as are heating and ventilation. Special forms of building are also treated as separate subjects, as well as the various equipments. For instance, we find lectures on the necessary appliances for hospitals, prisons and libraries. Building legislation is, moreover, not overlooked. Turning to the lectures which are given in other sections we find those on mathematics, physics, statics, geology, chemistry, book-keeping and general elementary law included in the curriculum of the general science division, and in another department the housing of the working classes—in fact, there are few German requirements which are not fully attended to at this college. I use the expression "German requirements" advisedly, for sanitation, which really occupies a very secondary position in a German architectural practice, receives similar treatment at this institution. And again, the measuring-up and sketching on the spot, which we consider so important, the German architect does not appear to appreciate, and as a subject of study is almost overlooked in the Berlin curriculum. Of course, the student has to select his own subjects, and to distribute them over the four years which he spends at the technical college, and if we turn at random to the list of subjects taken up by a first-year man on, say, a Tuesday, we may probably find that in the forenoon he attends lectures of an hour each in mathematics, elementary construction and a class of elementary drawing, and in the afternoon, perhaps, a lecture of one hour on geology or materials, followed by a class of elementary draughtsmanship of from two to three hours' duration, and including, say, instruction in the Classic orders. If we were then to take a fourth year's student list for the same day we might, on the other hand, find a two hours' lecture on the history of architecture and a two hours' class on design in the Renaissance style; then, in the afternoon, he may give a couple of hours to practical design, such as the planning of public buildings, and attend an hour's lecture on heating and ventilation. From these examples it will be seen that, in the earlier stages of the Berlin student's work, he seeks to obtain a foundation in draughtsmanship and science, while at the latter end of his course he devotes most of his time to the designing of buildings, some historical study and to gaining a knowledge of special equipment. It would no doubt be interesting to follow the architectural student's career from year to year or from term to term, but this would take too long, and I therefore only quote a couple of examples from a student's time table.

But now, after these historical and descriptive notes on the Royal Technical College at Berlin, I would ask if there are any disadvantages in the system of architectural education adopted by the Prussian Government? To my mind, though the opportunities for study are delightful, there is obviously something wanting in the whole system. Every preparation is made for the student to obtain knowledge, yet the result is by no means as satisfactory as might be expected. Does not this arise primarily from the student starting fresh from school without any previous elementary practical knowledge of construction? He has never been on a building in the course of erection, and does not know the difference between a piece of oak and a piece of deal. Neither, owing to his not having seen an actual moulding cut, has he any idea of the method of its production. For four long years he spends nearly his whole time in theoretical study, and as far as my own experience goes, there are but few men who utilise even the smallest part of their leisure in getting some idea of the nature of practical work. Does not a school where merely the theory of architecture is taught have a tendency to produce an architect of an academic character, though of course there may be the usual exceptions of brilliant and talented men, or those who are ambitious and energetic, and who do not follow the lines laid down for them? Do not many of the masters, too, in such a school soon lose all touch with practical work, and though brilliant scientists or historians, on receiving their professorship do not they lose all sympathy with the movement of the time, and even, by going through the same course regularly year by year, become mechanical and uninteresting in their methods, inspiring no enthusiasm in their pupils whatever? I think there can be little doubt that, just as it is at Berlin, for instance, the best and most popular masters are those few who keep in constant touch with current thought and practice.

As to the remedy for any unsatisfactory results, would it not be advisable that a boy should have a whole year's practical work in an office, with the run of some works for at least six months, before he starts his elementary studies at the college,

and should not every six months of theoretical study be interspersed with three months of practical work? Should not lessons in design be accompanied by lessons in the measurement of existing buildings, to enable the student to grasp the appearance of what he is putting on paper? Would it not be well, too, that the instructors in design, construction and in special equipment should one and all be men actually in extensive practice, and that such subjects as history, the elementary sciences and freehand drawing should be left to men whose vocation is chiefly to impart knowledge, yet who should be compelled to keep themselves abreast of modern progress?

We have had under consideration an establishment organised on the most elaborate lines, in which there is but little left to improve, as far as the syllabus of the classes is concerned. The Berlin Technical College has been on its trial for over twelve years, and the results, to my mind, are not all proportionate to the amount of time and money expended by the architectural student and the Prussian Government. Indeed, as the Berlin Technical College is in many respects a model to those advocating architectural education, so it must also serve as a warning to those extremists who would advocate merely theoretic study as the primary basis of a training in architecture and its actual practice. Much as we can learn from leading men in special technical subjects, the Berlin College only too plainly shows what harm can be done by taking an able man entirely away from his profession and thus preventing him from keeping in touch with that practical work which brought him into prominence.

I would conclude by saying that the architectural school at the Royal Technical College of Berlin is an institution well worthy of our attention and in many respects of our imitation, but at the same time we must observe the disadvantages of too theoretical an education and their evil effect upon a student destined for actual practice. What I have said in regard to the architectural school I believe holds good in many respects for the several engineering divisions of the same college.

## BIRMINGHAM AND MIDLAND INSTITUTE.

A LARGE party of members of the archaeological section of the Birmingham and Midland Institute and their friends had the privilege of visiting The Nash, the seat of Sir Richard Temple, Bart., on the 12th inst. After reaching Worcester a pleasant drive of six miles brought the company to their destination, where they were cordially received by their host, whose thoughtful kindness had even prepared handsomely-printed programmes, in which all the many articles of interest which awaited inspection were noted and classified in the order of their artistic and archaeological value. The Nash, being a private residence in a somewhat secluded neighbourhood, appears to be little known, but its own beauties and the objects of value it contains are remarkable. The house presents at this moment the appearance of a delightful ivy-clad Elizabethan manor-house, and the greater part of it would be correctly so described. But the original mansion must be of much earlier date, as may be seen by the enormous thickness of the walls in certain places—capacious closets being actually ensconced in them. Several of the rooms are of great interest, being practically unchanged since the days of Shakespeare and of good Queen Bess. In this respect the dining-room is conspicuous. The old Elizabethan oak panelling, which, after being painted most of the colours of the rainbow, has been carefully restored to its original simplicity by the present owner, is yet more recent than the singularly fine ceiling in elaborate plasterwork, and the hooks for supporting the tapestry, which the wainscot replaced, were discovered in the course of recent renovations. The overmantel is an elaborate and beautiful religious subject, apparently Italian. The hall is also a very fine room, and there are peculiarities in the domed ceilings of two apartments and in other internal arrangements which are deserving of careful study. The bedrooms are delightfully quaint, unexpected in shape, prodigal of unlooked-for corners and suggestive of perfect comfort. The range of the Malverns is seen from all the principal apartments. But neither the house nor its sweet pastoral setting form the exclusive charms of The Nash. Every room is crammed with the accumulated treasures of a family which, while rendering historical service to the State, has always retained a remarkable love for literature and for the arts. The walls are covered with the paintings of three generations, among which the vivid depictions of Indian scenery by Sir Richard Temple himself are conspicuous. Rare prints, choice furniture of all ages, from Tudor times to the Sheraton period, decorative paintings on marble, attributed to Angelica Kauffmann, a well-arranged and most attractive library, medals, miniatures, old china, priceless autographs, collections of Indian arms, fine overmantels, trophies of the chase and family portraits are everywhere in bewildering profusion. Even with

the unremitting attention of the ever-courteous host a long afternoon proved too short for more than a superficial inspection of the treasures of The Nash, while the beauties of nature, at their best on a perfect summer day, perpetually distracted the attention, and presented in every window-frame an incomparable picture. The work of investigation was agreeably interrupted by tea on the lawn, where may be seen a large and elaborately-carved font of Norman work, and was cut short by a supper, at which Sir Richard Temple insisted on being the host.

A hearty vote of thanks was accorded Sir Richard Temple, on the motion of Mr. Lawson Tait, for his cordial reception and exceedingly genial hospitality.

### DELFT-WARE.\*

DELFT-WARE takes its name from the little town of Delft in Holland, which well deserves the title of "Parent of Pottery" that has been applied to it. For nearly 250 years the fabrication was continued, and at one time as many as thirty factories were in operation.

During all this long period no other special manufacture was carried on, and we have the singular spectacle of an isolated town taking up an entirely new industry, raising it to its highest perfection, and maintaining its unique position against all rivalry up to the very last, when the time had come for enamelled earthenware to give place to stoneware and porcelain.

It is true that the potters of Delft formed themselves into a guild and took all the steps which were then available for retaining in the same spot a trade that had once become domiciled there, crushing out as they arose the various factories that were started from time to time in other Dutch towns. But these methods were necessarily powerless against foreign competition, and the long pre-eminence of Delft must be attributed to the superiority of its productions, assisted no doubt by the commercial activity and maritime enterprise of Holland. There are of course natural ceramic centres like Staffordshire, where pottery of some kind has always been produced, and numerous towns can be mentioned, such as Rouen and Nevers in France, and Bristol in England, which have become celebrated for the fabrication of wares of the same class as those made at Delft, but in no other case does the fame of a town rest solely upon a single kind of earthenware, manufactured there with but little variation during a period extending over centuries.

It has been shown by M. Havard† that before the closing years of the sixteenth century no pottery or faience was made at Delft. In the fifteenth and sixteenth century the town was celebrated for its breweries and for the manufacture of cloth. The latter is, perhaps, the older of these two industries, for it certainly goes back to 1413, but the brewing was an important part of the trade of the town as early as 1450. The Delft beer acquired a considerable reputation, and there was a time when nearly 300 little breweries bordered its canals, and exported their products to all parts of Holland. In 1536 a terrible fire destroyed almost the whole of the town. In consequence of this catastrophe, the Emperor, Charles V., exempted the citizens from direct taxation and the Delft beer from excise duty for a term of twenty years. About 1573 the Stadtholder, William the Silent, took up his residence in Delft, and it was there, in the Prinsenhof, facing the old church, that he was assassinated on July 10, 1584. The presence of the Stadtholder's court at Delft had rendered the town to some extent an artistic centre, and the higher arts of the goldsmith, the tapestry-maker and the wood-carver or cabinet-maker were called into existence. William's son, Maurice, was elected Stadtholder in his place, but he never resided in Delft, so that after a brief period of political and social prosperity the town was left in 1584 to fall back upon its industries alone. At this time the manufacture of cloth seems to have died out, and the breweries were beginning to decline, but within a few years Herman Pieterz was destined to introduce the beautiful art which was to give to the town its real celebrity.

The evidence which has led M. Havard to assign to the years between 1596 and 1611 the date of the introduction of the manufacture of faience into Delft seems to be quite conclusive. He finds that all the official documents relating to the town are in perfect accord in this respect. Those of an earlier date than the seventeenth century are absolutely silent on the subject of pottery; one indeed, of 1596, is of exceptional interest, as it gives a list of all the trades permitted to be carried on in the town, and in this list the potters are not mentioned. In the book containing the decrees of the magistrate the first mention of pottery occurs in the Act constituting the Guild of St. Luke in 1611. The "Masters' Book" of the Guild begins

with 1613, and at that time there were inscribed the names of eight master potters, the first of which is Herman Pieterz.

M. Havard has divided the history of the fabrication of the ware made at Delft into three periods. The first period, 1596-1650, is characterised by an extremely full decoration, generally executed in blue, the subjects represented being principally battles, historical scenes, &c., frequently containing great numbers of figures. Pieces of this period are very scarce, even in the large museums, but a fair number of specimens are to be seen in the Rijks Museum at Amsterdam.

The second period, which we may take to be 1650-1710, is chiefly remarkable for the wonderful imitations of oriental porcelain, not only in blue, but also in red, green, yellow and gold. The so-called cachemire decoration and the superb work of Pynacker, Fictoor and Van Eenhorn, who applied polychrome decoration to a black ground, belongs to this period. The blue and white ware also underwent development and improvement. The painting often displays great talent; most of the subjects represented are Chinese in character, but there are also many charming landscapes and rural scenes.

The third period, extending from about 1710 to the end of the fabrication, was entirely commercial. Every kind of useful and ornamental article was manufactured in immense numbers and transported to all parts of the world. The quality of the work was of every degree of excellence and badness, and the decoration in every variety of style.\*

The fine and hard wares of Staffordshire became serious rivals to the softer and less durable faience, and the struggle for existence was being keenly felt, even as early as 1760, among the Delft factories. Of the thirty which existed in the town at the beginning of the century but ten survived till 1794, all in a more or less languishing condition. The manufacture, however, still lingered on until 1850, when the last factory was closed.

In order to appreciate properly the qualities of any piece of pottery, some knowledge of its technique is required, and this is especially the case where, as in delft-ware, the painting takes place upon a crude surface. It will therefore be convenient at this point to give a brief account of the process of manufacture.

The clay was thrown or moulded in the ordinary way and submitted to a first firing. The article was then dipped in a white liquid, the dense matter in which formed a white coating to the body of the earthenware. The painting was effected on this white porous substance. The article was then covered with a transparent glaze and fired again. In the second firing the white coating and the glaze were both fused, the former becoming a white enamel, generally of a milky hue, and the latter a thin layer of glass.

Both firings took place in the same kiln, but a higher temperature was required in the second firing to fuse the enamel. The articles in their raw state were placed for their first firing at the top of the kiln where the heat was less.

Leaving for the moment the exact constitution of the white liquid, it is sufficient to say that the opaque white matter held in solution consists of oxide of tin mixed with oxide of lead and other substances which became fused in the second firing. The clay in its biscuit state after the first firing is very absorbent and when dipped into the liquid rapidly drinks in, so to speak, the water, leaving behind upon the surface a white coating of solid matter. In order to paint upon this spongy substance, which may be compared to blotting-paper, very great dexterity as well as suppleness of the hand is required, which can only be acquired by early training and long practice. The difficulty is increased by the nature of the paints which are formed of a mixture of the colouring matter, itself very fluid, with pure water without the addition of gum or any other substance to give cohesion.

On account of the excessive "thirstiness" of the ground and the very liquid character of the pigments, the artist has to manipulate his brush with great skill and quickness, for the least delay or hesitation on any spot causes too much of the colour to be absorbed there, and spoils the piece. The sharpness of the contours depends upon the limpidity of the colours and the rapidity of execution. Very rapid work is also required for shadows, as otherwise, however limpid the paint, they become thick and dark. The moment the artist takes the brush in his hand he has to decide upon the exact amount of intensity to give the contours and shadows, as no subsequent rectification or alteration of the work is possible. It is clear that painting executed upon so uncongenial a substance cannot be very accurate or exact in detail, but the boldness and vigour imposed by the conditions give to the finished work a special character and charm which is quite its own. Patience and care were not the qualities required in the artist, but there was ample scope for the display of originality and dexterity, and in spite of the difficulty of working upon a spongy and absorbent surface effects could be produced of the most surprising delicacy.

\* The amount and extent of the exportation by sea in the last century is shown by the fact that in England and the United States delft was the general name for all kinds of plain domestic earthenware as distinguished from fine wares or china. The word is still used in this sense.

\* A paper by J. W. L. Glaisher, Sc.D., F.R.S., read before the Applied Art Section of the Society of Arts.

† *Histoire de la Faience de Delft*. Paris, 1878.

For my own part, I cannot bring myself to feel any satisfaction in painting executed upon the glaze. The surface is hard, and there is no intimate connection between the painting and the manufacture to which it is attached. The colours are fired at a much lower temperature than that required to produce the piece, in fact only just so much heat is applied as will make them adhere to the glaze. Such an addition to the surface of pottery or porcelain is no real part of the object. It is frequently even worse than an unsuitable excrescence, as it may effectually conceal the whole of the ware itself so that its substance might just as well have been plaster or metal. In the case of Delft, the colours are part of the actual ware itself, incorporating with the enamel and modified and brightened by their contact with the glaze through which they are seen. The body, enamel, colours and glaze are all fired together at the same high temperature and form a single work of art, complete in itself, unproducible by any other method, defiant of the attacks of time.

Although the wonderful pieces of the middle period, in which the ground is sometimes black or green or yellow, and where gold has been freely applied to heighten the effect, are very interesting and beautiful, and extremely precious on account of their great rarity, it seems to me that the real charm and beauty of the ware is to be seen in its highest perfection in some of the pieces decorated only in blue upon a white ground. The blue combines with the enamel, entering into it and blending with it, and if the firing has been successful the colour is pure and bright without undue brilliance or self-assertion. In the best specimens, where the painting has been executed by a master's hand, and all the circumstances of the firing have been favourable, there is a softness in the blue, melting into the white of the enamel—or rather, so to speak, absorbed in it—and seeming to lie deep down beneath the glaze, which gives a peculiarly charming effect, not only to the decoration but to the piece as a whole. However beautiful the polychrome work may be, it seems to me that the best pieces of "coloured delft" are not comparable to those which are decorated only in blue. None of the other colours assimilate themselves so well with the ground; the reds and red-browns often seem to lie upon the surface of the enamel without entering into it at all, and even the yellows are very rarely quite satisfactory.

In these remarks I am referring only to really good productions which show the capabilities of the ware. The decoration of the ordinary run of moderately good pieces is effective and often striking when seen from a distance; but they will not bear a closer inspection—indeed, when a piece is looked into it is sometimes difficult to understand how the rough outlines and patches of colour can form so good a design and show off so well. The collector, however, occasionally meets with specimens which lose none of their charm when carefully examined; the general effect of the painting, of course is lost, but the softness and beauty of the colour and enamel are even more delightful.

As has been already stated, the date of the origin of the manufacture at Delft of earthenware covered with a stanniferous enamel can be established to within a few years, for before 1596 there was no factory in existence, and by 1613 there were eight master potters. It seems to be certain that Delft has no previous ceramic history, and that the making of faience there was not a development of an earlier industry, but was introduced as a new and complete art.

In the case of Rouen, which it is natural to refer to now as being, next to Delft, the most considerable seat of the manufacture of stanniferous faience, it is known that tiles were made there by Abaquesne in the middle of the sixteenth century. Then comes a gap of nearly a hundred years, till 1647, when there is evidence that faience was again being made. The date of the commencement of the fabrication on an extensive scale may be taken to be 1673, when letters patent were granted to Louis Poterat for the establishment of a factory of "faience and porcelain" at Rouen. In 1722 there were eleven important factories, employing 2,000 workmen, and as late as 1783 there were eighteen master faience-makers. Towards the close of the century the manufacture languished and declined, owing to the same causes which produced the decadence of the Delft factories.

Next to Rouen in amount of production must be placed Nevers. The manufacture of faience in this town began earlier than in Rouen, and covers a much longer period of time, extending from 1608 to well into the present century.

It cannot be doubted that the manufacture of earthenware coated with a stanniferous enamel was introduced into Holland and France from Italy, for the material itself and the mode of manufacture do not differ essentially from the majolica generally associated with the name of Luca della Robbia, which had been made in various Italian towns for the previous two centuries. We know that the founders of the industry at Nevers came from Italy and we should expect that it would have been the same at Delft, but Herman Pieterz was born at Haarlem and we find no Italian names among the early Delft

potters. This is very remarkable, as the processes of manufacture at Delft show a closer connection with those which had been employed in Italy than is the case with French faience. It would seem, therefore, that the art must have travelled from Italy to Delft by the way of some other Dutch town. In the letters patent of Louis Poterat it is stated that he has found the secret of making "la véritable porcelaine de la Chine et celui de la fayence d'Holande." Thus the first important factory at Rouen was founded for the manufacture of the kind of wares which were then associated with Delft. The date is so late that of course we should not expect direct relations with Italy. It is known that some of the workmen came from Nevers, and their influence is seen in the earliest pieces.

Rouen is associated with several very well-marked styles of decoration, some of which were perhaps derived from tapestry, lace, ironwork, &c. The name suggests at once the radiating designs—the decorations "à lambrequins" and "à broderies"—the cornucopia design ("à la corne") and a few others. There are also certain special styles associated with Nevers. But in the case of Delft, it is not easy to think of any classes of decoration which can be selected as characteristic of the fabrication in the same sense; of course, there are many common designs which were reproduced over and over again, just as the willow pattern has been repeated on stonewares in this country, and which at a glance tell the origin of the piece, but they cannot be said to have enough character to be actually distinctive. It is really for the immense variety of its designs that Delft was so remarkable; there seems to have been no kind of decoration either upon Oriental or European porcelain, or any other class of ware, that was not copied and developed. Many rustic scenes and landscapes are obviously Dutch in style, but they do not bear a sufficiently large proportion to the whole to be regarded as representative of the production of the town.\*

Just as Nevers is celebrated for its early pieces in white on a beautiful "bleu de Perse" ground, so may the pieces by Pynacker, &c., be counted as one of the chief glories of Delft.

If the ware itself, as well as the decoration, be taken into account, I think that the imitations of Chinese porcelain are perhaps the most characteristic products of the town. It seems strange that it should be possible to regard a copy of another material as characteristic, and yet none of the rivals of Delft produced in any quantity a ware so curious or admirable. The imitation is often so good that even a practised eye would be deceived at a little distance as to the origin of the piece, but when examined closely the enamelled earthenware has a certain softness which is particularly attractive. The first period of the fabrication seems to be distinguished by the absence of Chinese designs, but afterwards, when Oriental china was imported into Europe on a large scale, the great mass of the decoration of the Delft pieces shows a Chinese motive. The general tendency of the times to copy Oriental designs may have been increased by the fact that much of the trade with China was carried on by the Dutch East India Company, one of whose dépôts was at Delft.

It is not impossible that some of the pieces made at Delft were meant to be forgeries, but it is sufficient to suppose that the wider knowledge of Oriental porcelain had inspired an interest in the ware, which led to a demand for pieces of a similar appearance. The skill with which the enamel and

\* Among designs that have specially interested me I may mention "dragons" and "tea-plants." The former consists of a four-footed dragon upon a background of leaves, flowers and twigs, surrounded, in the case of plates and bowls, by a border consisting of a diaper pattern alternating with white concave spaces containing a conventional design which is always the same. It is curious to notice the persistence with which the accessories of the design are repeated. Thus, in plates and bowls the dragon and leaf-ground are surrounded by a white space bounded by two concentric circles and quite destitute of decoration. Then comes the diaper border and a red-brown edge, when the decoration is in blue. In nearly every instance all these details occur without variation. The artists also have allowed themselves very little latitude even in the painting of the dragon. The "tea-plant" (so-called by the Dutch dealers) represents a bushy spreading tree having a curious scar on the trunk; the branches are divided into three tufts above the central portion, which contains two flowers resembling eyes. In this design, which is pretty and effective, there is much less uniformity, and it is interesting to examine the variations in a collection of specimens. Both designs are obviously Oriental, but I have never succeeded in seeing an Oriental piece which has a real resemblance to either. It has often been remarked that Delft plates, unlike their Oriental originals, were very seldom decorated on the back. When there is any attempt at decoration it generally consists merely of a few concentric circles or of o's and crosses placed alternately at wide distances on the part of the plate outside of the flange. The best-known Delft pattern, and one of the most striking, represents a vase containing flowers with a radiating feathery background, the whole design giving the effect of an expanded peacock's tail. Many other patterns, besides those derived from Oriental porcelain, "Water and Ducks," "The Hart," &c., will at once occur to any collector, but the variety of the designs is so enormous that I think that, no matter how many a collector may have seen, he is always liable to be surprised by curious novelties.

glaze were manipulated so as to resemble porcelain so closely, both as regards general appearance and the "shine" of the surface in various lights, is truly remarkable, but it is in the ware itself, independently of the accuracy of the reproduction, that I find the fascination. For myself, I prefer the specimens in which there is little or no Chinese motive, and even if quite undecorated, some pieces would be very attractive solely on account of the charm of the material.

Vast numbers of tiles were made at Delft and, as in the case of the other wares, they were of every degree of merit. In most of them the decoration is in blue, but it is often in violet-brown; polychrome tiles are much less common. As a rule the painting is rough, and in many cases, where the subject is religious, the treatment is somewhat grotesque; but occasionally sets of tiles are met with in which the painting is as good as on the best plates. The large plaques made of tiles are characteristic and date from a very early period of the fabrication. A great many of these plaques are exhibited in the Amsterdam Museum, but it is not easy to see good specimens elsewhere. Solid plaques (in one piece) representing landscapes, birds in cages, dogs, &c., were also produced in considerable quantities; this kind of plaque was also made at Rouen and other places.

When we consider shapes, there are several kinds of vases which instantly suggest Delft as distinguished from Rouen or other centres of production. I do not suppose that any of the shapes could have originated at Delft, but such enormous numbers of these vases were made that they are now to be seen in nearly every bric-à-brac shop of Western Europe. The forms most usually met with are either circular or somewhat flattened (frequently octagonal in reality), decorated with a scene in front, but with merely a rough ornament in the back and sides. These latter vases may fairly be regarded as representative of the town, although the majority of them do it little credit. I think it would be found that most of the shapes attributed to Rouen by French writers had been previously made at Delft, for I have several times obtained early Delft pieces the shapes of which would be classed as "Rouen." The sets of five vases (garnitures) for the decoration of chimney-pieces, &c., were made in great numbers; some of them, dating from the early part of the last century, are very beautiful and striking.\* Great quantities of curiously shaped pieces (dishes in the form of birds, vegetables, &c.) were produced. The larger objects of this class, although interesting ceramically, are not very attractive,† but many of the smaller modelled pieces (cows, &c.) are excellent. I do not think that the very large modelled pieces (such as dogs, &c.) intended for use in halls and out of doors, and for which Rouen is celebrated, were made to any great extent at Delft.

No one who is fond of the faïence of Delft can help regretting that the factories struggled on so long. A great deal that was produced after the decadence had well set in is so poor and commonplace as almost to justify even a connoisseur in taking a dislike to the whole ware. The colours are harsh and aggressive, the painting itself is bad, and sometimes the enamel is coarse, so that it seems incredible that the same process could ever have produced fine ware. It is not uncommon to see pieces belonging to this last period in which the enamel is fairly pure and good, though the painting is horrible.‡ Up to the very last some of the blue pieces seem to have been pretty good, but I do not think it likely that any good polychrome work was produced during the later years of the decadence.

Nevers resembled Delft in having a long period of decadence, but the French Revolution supplied the motive of the decoration, so that the "faïences patriotiques" of Nevers, though not in any way superior as works of art to the contem-

\* In many of the vases the moulding of the lions, dogs, &c., which form the tops of the covers is very bad. I have seen "garnitures" in which the painting on the sides of the vases was excellent, entirely spoilt by the clumsy modelling of the tops, which look as if they had been half melted in the firing; the blue, too, has often lost its brilliancy and become dark and heavy. This is curious, as some of the separately modelled pieces of the same size are so admirable.

† One reason why these larger pieces, which are generally decorated in polychrome are so unsatisfactory, is that the reds are dull and bad in colour. It seems as if the glaze, which covers the blues and greens with a thin layer of glass, entered into combination with the reds, when spread over a considerable area, giving them the appearance of having been painted afterwards and not fired at all. The yellows are sometimes bright and entirely covered by the glaze, but sometimes they share the fate of the reds. When red is sparingly used on a white ground, as in pieces by Pynacker, it shows well, but in large objects, all covered with colour (as for example in a vegetable-dish shaped like a cock), the extensive areas of dull brownish-red and yellow deprive the piece of the very qualities for which the ware deserves to be admired.

‡ In many of the plates made at the "Claw," and having the design, already referred to in a note, of the "expanded peacock's tail," the enamel is very milky and attractive, and the painting quite satisfactory. These plates are so numerous that it would seem that this must have been the principal design in use at the Claw and Blompot in their last days.

porary wares of Delft, possess a peculiar historic interest which will always render them valuable.\*

I now come to the distinguishing point between the wares of Delft and the French stanniferous faïence. This consists in the fact that the former was covered by a transparent glaze which is absent in the latter. At first sight it would seem difficult to understand how the glazing was effected without a third firing, as the dipping the painted enamel into a liquid glaze would cause the colours to run. The method is described by Gerrit Paape in his work of 1794, which has been reproduced in French by M. Havard. The workman dips a short rough-haired brush into the liquid and shakes it violently to get rid of the excess. He then sprinkles the object to be glazed, which he holds in his hand, until it is as white as snow. This process, according to M. Deck, was not followed by the French makers of faïence. The glaze not only has the effect of heightening the colours, but it also protects them from evaporation, and indeed to me it seems that it is just this glaze that gives to the best wares of Delft their superiority over those of Rouen and Nevers. The difference in effect is not very noticeable at a distance, especially if the design be large, but it becomes very evident when a closer inspection is made. Without the glaze it would have been impossible for the Delft potters to produce their wonderful imitations of Chinese porcelain, and to anyone who has become accustomed to the brightness of the best Delft pieces the dull and faded appearance of much of the most admired French faïence is very disappointing. How this essential difference between the French and Dutch processes could have arisen, and why it should have always continued, is difficult to conjecture. It is known that the Italian majolica was covered by a glaze of somewhat similar composition to that used at Delft, and it is almost impossible to resist the conviction that the process must have passed from Italy to Holland. So far as I can see, the glazing process was carried out in the English delft factories, and we should expect this to be the case also in other countries where the manufacture was introduced from Holland.

It is probable that Delft not only trained the best painters and workmen, but that it always retained their services; and it is, I think, unquestionable that the finest pieces of delft-ware (*i.e.* earthenware covered with a tin enamel and a lead glaze) that have ever been produced were made there. The general superiority of the wares of Delft over those manufactured elsewhere, even by Dutch workmen, must, however, be attributed to the excellence of the mixtures of clays adopted there, which gave to the body of the ware just the right porosity to deposit the proper thickness of enamel, and produced a contraction during firing that was in perfect sympathy with the enamel, so that there were no cracks or other signs of crazing.

Gerrit Paape states that the clay employed at Delft was obtained by the mixture of three different clays, *viz.* the Tournai clay, the Rhine clay, and the Delft clay, combined in the proportions of six, three, and two. He mentions that the Tournai clay was often replaced by that of Brabant, and that the Rhine clay came from the neighbourhood of Leyden, and even of Delft itself.†

M. Deck, referring to French factories (Rouen, Nevers, Moustiers), remarks that the composition of the enamel was the same, and that the great differences in the appearance of the pieces are due solely to the quality and properties of the local clays. I think we may assume that this is substantially true generally, the great variations in the quality of the products of the different towns being attributable almost wholly to the nature of the clays, so that the composition of the enamel (except as regards tint or colour) need not be taken into account. The body of the ware made at Delft was buff-coloured after firing and is very light in weight. The pinkish appearance seen under the enamel in so many English pieces is, as is well known, due to the less absorbent quality of the English body, the reddish hue of which shows through. Pieces made in the North of France (Desvres, &c.) or at Brussels or Bruges are often as well painted as those of Delft, their inferior quality being obviously due merely to the hard and coarse body, too thinly covered by the enamel. I have frequently met with plates in France, possibly made at the minor factories, which, though elaborately and excellently painted in polychrome, were quite spoilt by their dull and blistered appearance. At first sight it would be natural to regard these as good pieces which had gone wrong in the firing, but they are too numerous to be

\* The only corresponding products of Delft are the plates representing Prince William V. and the Princess Sophia Wilhelmina, generally separated by an orange tree. These plates must have been made in enormous quantities, judging by the number that are now to be met with. The "patriotic" designs were also painted on English stone ware and exported into Holland.

† It is noticeable that Delft seems to have possessed no special natural advantages for the making of earthenware. The clays used would have been available also for other towns, which probably would have been equally well placed as regards water carriage. The conditions were such, however, that when Delft had gained the trade, it would clearly be difficult for any other town to deprive her of it.

so explained, and I think that the bad result must be attributed to an unsatisfactory body and the absence of a glaze.\*

The ordinary German delft-ware are easily distinguished from those made at Delft. The blue is raw and harsh and the quality is poor. As a rule the softness which characterises the good ware of Delft is quite absent. In the districts near Nuremberg, and probably elsewhere in Bavaria, great numbers of tankards, generally decorated in polychrome, were made, and some of these are comparable to the products of Delft itself, though in most cases the true "shine" is missing. In quite a number of pieces the enamel itself is coloured (green, yellow or blue). Sprinkled or mottled grounds, such as are in this country associated with Liverpool, are also common in Bavaria.† The Zürich delft is not unlike that made near Nuremberg; but the body of the delft-ware of Winterthur is so hard and the enamel so thin that it is of quite a distinct character. On the whole, I think that next to the English delft the products of Zürich and the region around Nuremberg have the closest general resemblance to the ware made at Delft. Most of the contemporary Italian and Spanish faïences, though technically to be classed as a delft-ware, as the enamel is stanniferous, are so different in character, being often dull and with a smeary appearance, that they need not be referred to here. It is curious, however, that some of the best pieces of white delft (scallop plates and drug pots), both as regards quality and glaze that I have seen, are (presumably) Italian.

The stanniferous enamel was composed of lead, tin, silica and alkaline substances. The lead and tin were first combined into what may be called the calcine as follows:—After the furnace had been lighted four or five hours the lead and tin were introduced (in bars or ingots) in the proportion of about three to one. The heat of the furnace was gradually raised, and when the metals had become perfectly liquefied a kind of foam was seen to form upon their surface, in which little bright stars flashed out from time to time. The oxygen of the atmosphere was then combining with the metals. The process was continued until the metals were completely oxidised.

A substance called mastic was formed by melting sand, sea-salt and soda in the proportions of 500, 60 and 30. When fused a fragile body was produced which was finely pounded.

The enamel or "wit" (white) was then obtained by fusing 50 parts of calcine, 65 of mastic, half a part of smalt and a small quantity of red copper filings. A very great heat was required to melt this composition, which was therefore placed in the hottest part of the oven. It was then pounded and ground to a great degree of fineness between millstones. This powder, when mixed with a suitable quantity of water, formed the enamel into which the objects were dipped in the biscuit state after their first firing. The smalt was evidently introduced in order to improve the colour.‡

(To be concluded.)

## LIVERPOOL SCHOOL OF ARCHITECTURE AND APPLIED ARTS.

THE annual exhibition of selected works done by the students during the past session was opened on the 11th inst. in the Applied Art Building. The exhibits include architectural drawings and designs by first and second year's men and more advanced students, modelling from the life, designs for fabrics, wall-papers, book-plates, stained-glass, posters, &c., and many charming and fanciful sketches submitted for the Sketch Club competitions. There are some specimens of wood-carving, and a few, but very excellent examples of wrought-iron work, which show that this class is educating the apprentices in this most important branch.

The exhibition conveys favourable impression, not only of the capabilities of the students, but of the lines upon which the teaching proceeds. An example is afforded by what may be called the premier department—that of architecture, which is under the direction of Professor Simpson, the principal of the schools. The collection of architectural drawings not only shows good, and in some instances excellent, draughtsmanship, but a thorough grip of the practical as well as the artistic side of architecture, as evidenced by the treatment of working details. This scientific thoroughness, the best foundation for artistic achievements, is insisted upon in every instance, but it

is interesting especially to note the several groups of drawings illustrating the treatment of the same subject by different students. The subjects in this instance are a two-storey façade in the Classical style; a doorway in the same style with arched pediment, and a complete set of drawings and plans for a small country mansion. The drawings show interesting individual treatment of the same principles, as well as the stimulus given to independent reflection and the use of knowledge. In regard to the department of modelling and sculpture, the main feature is the prominence given to direct study from the life. There is a beautifully-modelled bust by Mr. L. Crosfield, showing vigorous insight into plastic effect, the work having a strongly marked character. The series of models of a figure adapted for telephones and the half-dozen reliefs of a half-length female figure, a classical study for "Pandora," are instances of healthy emulation upon right lines. The reliefs and modellings of a more purely architectural character are also interesting. The same practical view is uppermost in the exhibits of the students of decorative design and painting—that is to say, the object of the school as one of applied art is obviously kept steadily in view by Mr. Anning Bell, since the designs are for friezes, wall-papers, posters, book covers, cushions, hangings and illustrations for periodicals and books and are of a strictly applicable character, whether in black and white or colours. The black and white work predominates and much of it is of distinctly fine quality, and while originality is fostered eccentricity is kept down. The examples of wrought-iron work are really admirable bits of craftsmanship and skill.

## ARCHITECTURAL ASSOCIATION OF IRELAND.

THE annual excursion took place on Saturday last. The members left Amiens Street for Drogheda, where brakes were in readiness to convey the party to Mellifont and Monasterboice. The route taken lay through the fine scenery of the valley of the Boyne and the beautiful demesne of Mr. R. H. Balfour, D.L., Townley Hall. At Mellifont Abbey a couple of hours were spent in measuring and sketching the remains of this fine old Cistercian foundation. The chapter-house in particular is in an excellent state of preservation, and affords much material for study by the architect and the antiquarian. After lunch at Mellifont, Monasterboice was visited and the round tower and two fine Celtic crosses were examined and sketched. The party then returned to Drogheda, where some places of interest were visited, including the old abbey, St. Laurence Gate, and a rather quaint Georgian building, now used as a police barracks.

## TESSERÆ.

### Westminster Hall and the Coronation of George III.

A PLATFORM was erected from the upper end of Westminster Hall, where the procession commenced, which continued through New Palace Yard, Parliament Street and Bridge Street into King Street, and so round through the west door of the Abbey on to the choir, where His Majesty was crowned. In view of this platform, the houses on each side were lined with scaffolding, the seats on which were let at the most exorbitant prices. The front seats in the galleries of the Abbey were hired at ten guineas each, and those in commodious houses along the procession at no less prices. The terms in ordinary houses were from one guinea to five, so that a small house in Coronation Row, after the scaffolding was paid for, cleared 700%, and some large houses upwards of 1,000%. In the coronation theatres, as they were called, which were large temporary erections, capable of containing from 1,200 to 1,500 seats, the prices were beyond all precedent, though some who fitted up houses and scaffolds on this occasion lost considerably through the greatness of their demands. The ground rent where the scaffolding was built was proportionately extravagant. That in the Broad Sanctuary was 3*l.* 13*s.* 6*d.* per foot, and that within the rails enclosing the Abbey was five guineas. For the celebrating of the coronation feast, Westminster Hall was laid open throughout, and everything it before contained entirely removed, excepting the floor and steps of the King's Bench Court. A new boarded floor was then laid from the north gate up to the middle of the hall to those steps, and covered with matting. On each side was built a large gallery, the lower part about 5 feet from the ground, and containing eight benches, covered also with matting, for the spectators. Over this was erected a second gallery, not so wide but of the same length as the open part of the hall when the King's Bench Court was standing; over which also a third gallery was fixed as it were in the roof, and supported by those beams which are decorated at the ends with figures of angels, being nearly the same length as the others but scarcely so wide from its being placed in a narrower part of the building. Between the first gallery and the floor were erected, on each side, large closets or pantries with double doors, answering the purpose of sideboards and cellarets, as well as to contain the plates, dishes,

\* It is a singular fact that the brightest delft plates that I have ever seen were met with in France. This would seem to suggest that the wares made by Aegestyn Reygens and others for exportation to France were especially brilliant.

† These grounds also occur frequently in Bruges pieces.

‡ The coloured enamels were of course obtained by introducing colouring substances into the constitution of the enamel, and this may have been effected in different ways. There are great varieties in the tint of the white enamel, much of it having a greenish hue. One form of border decoration associated in this country with Bristol consisted in "painting" with a pure or cream white enamel slip upon a greenish-white ground.

glasses, &c., wanted by the company and waiters. In a space left between these pantries and the platform up the middle of the hall the tables were placed for that part of the company who had not the honour to be seated with the king. His Majesty, with the queen, nobility, great officers of State, &c., dined in the elevated part of the hall, near the Court of King's Bench. The whole was lighted by fifty-two large chandeliers, each ornamented at the top with a gilt imperial crown. Over the north gate, opposite the king's table, was erected a large balcony for the trumpets, kettledrums, and other music, and in the centre over them was fixed an organ. It was under this music that the champion, attended by the Lord High Constable and the Earl Marshal, made their entrée on horseback into the hall.

### Greek Scholarship in England.

Among the first and most liberal encouragers of Greek learning was Humphrey, Duke of Gloucester, brother to Henry V. This royal "bibliomaniac of the dark ages," as he is styled by Mr. Tytler, earnestly laboured to banish the gloom of barbarism, in which England was in his time involved, by his own example as an author and a scholar, by a munificent and enlightened patronage of contemporary efforts of learning, especially of such as were directed to enriching modern Europe with Latin translations of the Greek classics—a labour in which the learned of Italy were at that time largely occupied—but especially by forming collections of the best ancient authors. Of the latter mode, his present to the University of Oxford of above 600 splendid volumes, written on vellum and elegantly embellished with miniatures and illuminations, was a noble example. It is deeply to be lamented that a single specimen only survives of this monument of Humphrey's taste and munificence—a beautiful manuscript, in folio, of "Valerius Maximus"—the rest, under suspicion of containing matter savouring of Popish superstition, having been sacrificed to the zeal or ignorance of the pious visitors in the reign of Edward VI. Among those patronised by Humphrey were Leonard Aretin, Piero del Monti, Petrus Candidus December, Lopus de Castellione, Tito Livio of Foro Julii, whom he constituted his poet and orator, and Antonio Beccaria his secretary, whose translation of six tracts of Athanasius, undertaken by command of the duke, is among the royal manuscripts in the British Museum. The first of those English scholars who studied the Greek language in Italy, then the only school of polite letters, are John Tiptoft, Earl of Worcester, Lord Chancellor to Edward IV., and John Free (or Phreas, as he is called by Leland). Tiptoft and Free, with Grey, Fleming and Gundorp, passed over from Oxford into Italy; and either together, or at no great interval of time from each other, became pupils of Guarini, of which celebrated teacher it is related, as a striking evidence how deeply interested his feelings were in the learned pursuits in which he was engaged, that having, while studying in Greece under the celebrated Chrysolorus, collected two large boxes of manuscripts, the loss of one of them, by the shipwreck of the vessel in which he was returning to Italy, caused him such profound concern that his hair became grey in a single night. Tiptoft brought back with him to England, whither he was accompanied by the Italian scholar Ludovicus Carbo, a valuable collection of manuscripts, intended both for his private use and to enrich the Humphreidian library at Oxford. These, after his execution, upon the restoration of Henry VI., were with some difficulty secured to the University by George Neville, Archbishop of York; under Edward VI. they followed the fate of the rest of Duke Humphrey's library. Tiptoft left several works in Latin and in English, at the end of his impression of one of which, a version of two orations of Banatusius Magnomontanus, Caxton has paid a tribute of enthusiastic affection to the memory of the accomplished earl. Of Free, we are told, there remain high encomiums from the pen of Guarini himself in the collection of his epistles preserved in the library of Balliol College. Johannes Anglicus (so Free was styled) stood so high in the estimation of the accomplished scholars of Italy that, when time or accident had effaced the original epitaph upon the tomb of Petrarch, he was requested to compose an inscription to succeed it more consonant with the approved Latinity of the age. Some of his works deposited in Jesus College, Oxford, have perished; those which remain are:—"Cosmographia Mundi," consisting of extracts from Pliny; a translation of some parts of "Xenophon;" a collection of ten Latin epistles, and a little poem, "Carmen ad miraculum usque elegans" (says Leland), addressed to Tiptoft.

### James Heffernan, the Sculptor.

Had James Heffernan met with a liberal patron in early life who would have afforded him the means and the opportunity he might have ranked high in the world of art, but he fell into the hands of a selfish and ungenerous man, Sir Francis Chantrey, who overshadowed his modest merit under the greatness of his name, and who, employing him as a mere drudge, reaped all the benefit of his cultivated mind and practical ability. Born in Londonderry in the year 1785, he quitted that city for Cork at the early age of eleven,

at which time he displayed great talent for drawing. Shanahan, with whom he left his birth-place, was engaged extensively in marble works, besides being occupied as an architect in considerable practice. That young Heffernan should try his prentice hand at such minor efforts with the chisel as chimneypieces and tombstones admitted of is but natural to suppose, especially of one whose love of imitation was manifested at an age when other boys are engrossed in tops or luxuriate in leap-frog. The love of the art grew upon him even before he approached the vestibule of the Temple; and from that time James Heffernan felt within him the divine impulses of genius, and those passionate longings after the beautiful which distinguish the true artist. With such aid as Cork then afforded the young sculptor studied intensely and toiled with unremitting energy, until he felt his strength equal to a bolder effort. When little more than twenty-two he left Cork for London, and was in a short time afterwards engaged in the studio of the sculptor Rossi, whose employment he left for that of Chantrey—an artist who owed much of his fame to the imagination of Allan Cunningham and the cunning chisel of the modest Heffernan. During his first connection with Chantrey he devoted himself to a study of sculpture with a perseverance which was followed in his case with the most beneficial results. After a sojourn in Rome he returned to London, when fate threw him in the path of his former employer, who lured him to his studio by promises which he never realised, and most probably never intended to realise. At any rate Heffernan remained with Chantrey till the death of the latter, in whose will, of course, there was no mention of his gifted assistant. The death of his faithless employer was of this advantage to him—that he was called on to finish some of his most important works, which he did in a manner that acquired for him both fame and emolument. But just as the path was being cleared before him, and he saw himself at last on the eve of realising the dream of his youthful ambition, his health failed him, and he was compelled to seek its restoration by the waters of that river which he loved from his boyhood. After a residence of some years in Cork he fell a victim to an acute disease in the month of October 1847.

### Memorials of Ancient Greek Triumphs.

Burglars in Athens swarmed like flies in a hot August with us, in fact, so plentiful that even the memorials dearest to their vanity and patriotism—viz. their battle trophies—could not otherwise be protected from the rapacity of domestic robbers than by making them of materials which would hardly pay the cost of removal. The Greeks, after any victory of one little clan over another—of Spartans over Thebans, or of Thebans over Spartans—used to do two things in the way of self-glorification; first, they chanted a hymn or *psalm*, which was their mode of singing *Te Deum*; secondly, they erected a trophy or memorial of their victory on the ground. But this trophy one might naturally expect to be framed of the most durable materials, whereas, on the contrary, it was framed of the very frailest, viz. firewood. Why the wood rapidly disappeared is therefore easy to understand, but not why it had ever been relied on as a durable record. The Greeks, who were masters in the arts of varnishing and gilding, reported the whole case in the following superfine terms:—"It is right and simply a necessity of our human nature that we should quarrel intermittingly. We Grecians are all brothers, it is true; but still even brothers must, for the sake of health, have a monthly allowance of fighting and kicking. Not at all less natural it is that the conquerors in each particular round of our never-ending battle should triumph gloriously and crow like 20,000 gamecocks, each flapping his wings on his own dunghill, armed with spurs each according to the Socratic model left us by Plato. An allowance, in short, of shouting and jubilation is but fair. Still, all this should have a speedy end, not only upon the prudential maxim that he who is the kicking party to-day will often be the kicked party to-morrow, but also on a moral motive, viz. to forget and forgive. Under these suggestions it becomes right to raise no memorials of fighting triumphs in any but fugitive materials; not, therefore, of brass or of marble, which would be too durable and would be too costly, but rather of wood the most worm-eaten, and if it shows signs of dry-rot all the better. Under this limitation our triumph puts on a human and natural shape. It very soon decays and typifies our exultation, which decays concurrently." The reason, therefore, for not using brass or copper was because in that case, long before the moon had run her circuit, the trophy would have been found in a blacksmith's shop at Corinth or Athens, sold or pawned at the rate of a drachma a head for a gang of forty thieves.

### Arundel Castle.

The earliest notice of the place occurs in King Alfred's will, where it is termed the manor (ham) of Erundellan, and it seems probable that the castle was one of those which he erected to guard the southern coast, and which, it is not unlikely, might at one period have been honoured as his residence. That a castle stood there in the time of Edward the Confessor is proved by

Domesday Book, in which the castle of "Harundell" is expressly mentioned as having rendered in the reign of Edward a certain payment for a mill; from the same document we learn that there was already a port and a town. Of this early castle it may well be supposed that little, if any, remains, and we must proceed to Norman times to trace the advancing splendour of the castle of Arundel. When the Conquest transferred nearly all the property to the retainers of William, the castle, together with the entire rapes of Arundel and Chichester, containing eighty-four and a half knights' fees, or 57,460 acres, were marked out to form "the honour of Arundel," which, with the title of earl, was bestowed upon a relative of the Conqueror, Roger de Montgomerie, who had commanded the centre division of the victorious army on the field of Hastings. It was under the superintendence of this earl that the castle of Arundel assumed the stern, but imposing, character of the Norman stronghold—arches adorned with the chevron moulding, unruined in the lapse of more than seven centuries, walls of 8 and 10 feet thickness, firm and strong as the work of yesterday, add another attestation to the superior ability of the Norman architects; while the "donjon," that proud appendage to the baronial castle, might still be converted into a place of captivity. Toward the close of the thirteenth century, Earl Richard, the third of the Fitzalans, greatly enlarged and improved the castle, while in the following century his grandson erected the hall, which, unfortunately, was wholly destroyed during the siege in 1643-44. But it was not until the sixteenth century that the castle was entirely completed, for then the north-east wing was added, and a splendid gallery erected. And thus might the castle of Arundel have stood, even to the present day, perfect in its ancient form, and altered only in its inferior appendages, had not the violence of civil discord intervened to destroy its glories and reduce the most venerable portion of its fabric to a ruin. From this time until the year 1720 no attention was bestowed on these ruinous remains. At that period, however, the Duke of Norfolk determined to restore the castle, at least to a habitable state; this determination was carried into effect by his son.

#### Early Greek Coins.

Early Greek coins, which were fabricated prior to the time of Alexander I. of Macedon, are generally characterised by having on the reverses indented squares or rude indentations; but some have an incuse (sunk in) reverse, answering, or nearly so, to the subject which is in relief on the obverse or head side. Some, however, have upon the reverse an indented object, different from that which is raised on the obverse, as may be seen in a very ancient coin of Metapontum; while the coins of Metapontum, Paestum (or Posidonia), Crotona and Caulonia have a dotted circle at the extreme edge. One of the most interesting coins of antiquity, and certainly one of the most ancient, is the gold Daric, which is said to have been first coined by Darius son of Hystaspes in the second year of the 64th Olympiad, or 522 before Christ; it is indeed doubtful whether there be any coins of greater antiquity. These gold Darics are of great purity as to the metal, but of a rude, irregular shape and coarse workmanship. They have on the obverse the figure of a king kneeling upon one knee, holding in the left hand a bow and in the right an arrow; upon the reverse merely a rude indentation. It was this type of an archer which gave rise to the pun that Agesilaus, king of Sparta, had been driven out of Asia by 30,000 archers, he having, it is said, taken a bribe of that amount from Artaxerxes to evacuate Ionia, where he had gone to free the Greek cities, then groaning under the tyranny of Persia. The most obvious peculiarity to be observed in this epoch is the indented or hollow square, which may probably have arisen in rude efforts to fix the blank piece of metal between the two dies whilst the blow was struck. The second epoch is from Alexander I. of Macedon to Philip II., or the 395th year from the building of Rome; and during this period we discover a considerable improvement, but still the peculiarities of the earlier coins are visible; we have still the indented squares on the reverses, but the name of the city where struck or of the king in whose reign appears, or there is engraved a head or some other object, or the same subject is repeated which appears on the obverse. Examples of this may be found in the coins of Acanthus, of Alexander I. of Macedon, of Thebes, of Syracuse, of Selinus, of Himera and of Argos. Towards the end of this epoch some remarkably fine coins occur, as in those of Amphipolis of Thebes (with the head of the Indian Bacchus), of Methymna, of Chios, of Chalcis in Macedon and many other specimens.

#### Sir David Wilkie and Dutch Art.

The works of Wilkie have contributed largely to the extinction of that erroneous prejudice which, too generally spread, maintained that the old masters were in possession of some method of preparing their pigments to the moderns unknown. In dexterity of execution he is perhaps not equal to Teniers, but in composition he is certainly as original, as natural, and in invention and expression superior, not only to

him, but equal to any artist of those schools—not even excepting Jan Steen. In the union of brilliancy and powerful effect, as combined with execution and finishing, perhaps, the famed picture commemorative of the victory of Waterloo is as high an example as can be produced in art. There is another picture by this artist, the *Interior of a Scottish Distillery*, which, quite in the gusto of these schools, is equal to any subject of the same class that can be named. There are, among other impediments to modern practice, however, two material difficulties, neither of which the old masters had the misfortune to experience. In the flourishing periods of the Dutch and Flemish schools the various painters were encouraged to paint whatever presented itself to their imitative powers. The everyday occurrences, and all the local circumstances of time and place, afforded subjects for their pictures. Hence they were spared the toil and inconvenience of research for themes. Their own families furnished them with living models; their own demesnes, however limited, with scenery; and their furniture with those accessories and expletives technically denominated still life. With this allowance, and thus abundantly surrounded with material, we are less surprised that their works exhibit so close an imitation of all the objects which compose their pictures. Of this first advantage, then, which was positive, they had the full benefit. The second, though negative, was, comparatively with modern practice, equally in their favour. Painting was admired then as an imitative art, when it was well executed, purely for its own sake. There were no former schools to compare their works by, to their certain prejudice, as in later times. Their pictures were only compared with the objects from which they wrought; and if the imitation was faithful the end was answered, and the patron and the patronised were mutually satisfied. Now the practice is widely different. He who expects to please the connoisseur must invent as well as imitate. Indeed it is so with the public at large. The localities of everyday life are not endurable as *thematæ* for the painter. If, however, he venture to attempt the costume of the day, he must contrive a story wherein the *dramatis personæ* are moved by some passion; for, without expression, and that not equivocal, the figures in a modern composition go for naught. It is with painting as with the dramatic art—local circumstance, according to modern taste, will form but an insipid play. He who would draw a crowded audience to his piece, built on the living manners of the times, must make his characters outrage truth. So he who would expect to sell a picture of things, with the localities of the nineteenth century, must do more than paint modern cabinet-work, with all its elegance, or homely spinsters at their writing-desks; though the silks and satins, carpets and stools, with all the accessories, little and great, were imitated, if possible, with even greater truth and skill than by the pencil of a Terburg, a Metz, or a Gerard Dow.

#### GENERAL.

**Mr. Frank T. Verity**, architect, has removed to No. 7 Sackville Street, Piccadilly, W.

**A Portrait** of two children in a garden, by Romney, was sold on Wednesday for 9,100*l.* It is from the collection of Mr. Cowper, of Penrith, and probably the original price was 100 guineas.

**The Sheffield City Council** have decided to ask the Duke of Norfolk to accept the mayoralty for a third year. A statue in recognition of his Grace's services to Sheffield is to be erected within the newly-opened Town Hall.

**At a General Assembly** of the Royal Society of British Artists, Professor Herkomer, R.A., and Professor Richmond, R.A., were elected honorary members of the Society.

**A Mace**, designed by Mr. A. Willms for the Birmingham Corporation, will shortly be complete. The head or bowl portion of the mace is divided into four panels, one of them bearing a bold representation of the city arms, while the others are occupied by emblematical devices. The panels are divided by leafage of oak, emblematical of strength. An open imperial crown surmounts the head. This portion of the mace is joined to the stem by brackets, formed out of the figure of Britannia, while the stem, suitably divided by bosses, will have spiral *repoussé* enrichment of oak and laurel. In the terminal boss will be inserted a crown piece of the present year's coinage.

**At an Annual General Meeting** of the Imperial Insurance Company, Limited (Fire), held at the company's offices, Old Broad Street, on Thursday, a dividend was declared for the year 1896 at the rate of 25*s.* per share, being an increase of 5*s.* per share over that paid for the preceding three years. As the result of the year's transactions, after providing for payment of that dividend, 57,449*l.* was carried to reserves, making them 868,688*l.*, and that sum, in addition to the paid-up capital (300,000*l.*) and special reserve (400,000*l.*), brings up the total funds of the company to 1,568,688*l.*

# The Architect.

## THE WEEK.

PUBLIC fêtes occur so rarely in this country it is no wonder we cannot produce them in a style that will bear comparison with French fêtes. In Paris the production of the accessories is a regular branch of trade, and consequently there is competition not only in price, but in style. Efforts are made to introduce improvements every year in one way or another, and the aid of artists is constantly invoked. In England there is a sort of monopoly, and the public are compelled to adopt "stock patterns" or to pay an enormous price for decorating a building. commonplace forms are consequently to be seen everywhere. On such occasions also co-operation is invaluable, if a successful effect is to be produced. Men who are rivals in Paris streets do not hesitate where there are fêtes to unite, for they know that a fine decorated street is a gain to all who have shops in it, while a single example of discord can spoil a long stretch of excellent work. The local authorities are also on their mettle, and are ambitious to hear their *arrondissement* or *quartier* praised for its effect, as in that way their influence is extended. The streets along which the procession passed this week were more creditable to the authorities than on former occasions, but it was too evident that the contractor was in most cases the arbiter of taste. The decoration of private houses varied to a remarkable extent, and it must be said there was a more vast display of crude colours than we had anticipated. But the people who used the flags and drapery would say they were helpless, for they could not obtain a piece of drapery in quiet colours without a search for which there was no time. Whenever there are shortcomings in public displays among us, it is well to take the goodwill rather than what has been accomplished. There was enough heartiness, loyalty and enthusiasm exhibited on Tuesday to inspire a whole year's rejoicings in any continental town. The individuality, of which the defects were a sign, was all concentrated on one idea, in expressing the general joy for so long and so beneficent a reign.

FOR more than a quarter of a century the erection of the Albany Capitol has been in progress. Work had to be undone as well as done. According to *Architecture and Building* the final contracts were to be signed by Governor BLACK a fortnight ago, and the work of completion will be under the direction of Superintendent of Public Works ALDRICH. The bulk of the work yet to be done comprises the finishing of the eastern approach and the southern and the northern entrances, and the carving of the western staircase. As soon as possible landscape architects will prepare a plan for laying out Capitol Park. The building of a central tower has been abandoned. The fifth storey of the Capitol will be left in an incomplete condition. It is used at present for storage purposes. Most of the stuff put there is to be auctioned off, as the Capitol authorities are apprehensive that damage may be done the building by the breaking out of fire on this unused floor. The entire cost of completing the Capitol (ground values included) will exceed 23,000,000 dols. But as the central tower will not exist, the building will be a disappointment to those who expected to have at Albany a rival to the Washington Capitol.

THE Plumbers' Registration Bill now before Parliament does not obtain the unanimous approval of some of the bodies having interest in technical education. The National Association for the Promotion of Technical and Secondary Education has passed the following resolution:—"That this executive committee is strongly of opinion that while it is very desirable that a register should be formed of competent plumbers, and that the register might be kept by the Plumbers' Company, the general council under the Plumbers' Registration Bill should be required to place upon the register those workmen who have passed the examinations in plumbing of competent public bodies approved by the Local Government Board and who apply to be placed on it; that, with respect to clause 9, the body upon whom should devolve, subject to the orders and supervision of the general council, the carrying out of the objects of the

Act should be a committee of members of the general council elected by the general council, to be approved by the Local Government Board." By the London Polytechnic Council, consisting of representatives of the City Parochial Foundation, the City and Guilds of London Institute and the Technical Education Board of the London County Council, the following resolution was also unanimously adopted:—"That this Council is of opinion that the objects of the proposed Bill, so far as regards the registration of plumbers by the Plumbers' Company, command the support and approval of the London Polytechnic Council, but that the Bill requires considerable amendment in the direction of the adequate recognition of the work and examination of the City and Guilds of London Institute, and of the substitution of some more representative body for the Plumbers' Company as defined by the Bill on whom shall devolve the carrying out the examinations and other educational objects of the Bill; also that the constitution of the General Council should be made less cumbrous and be more directly representative of educational authorities. That a copy of this resolution be sent to Mr. E. BOND, M.P., and that he be requested to secure the introduction into the Bill of such amendments as may be necessary to give effect thereto, and that copies of the same be forwarded to the Local Government Board and Education Department."

THE Board of Trustees have decided that the design for the New York Library is to be obtained by a dual competition. The building is to stand on a site at the east end of Bryant Park, measuring 482 feet by 455 feet. The building is to cost 1,700,000 dols. All architects having offices or fixed places of business within the limits of Greater New York can take part in the first competition. This preliminary competition will be judged by the committee's present advisers, Professor WARE, Mr. BERNARD R. GREEN, the constructor of the new Congressional Library, and Dr. J. S. BILLINGS, the director. For the twelve sketches which in their judgment are the most meritorious will be given a premium of 400 dols. each. The committee will then choose from the authors of the twelve sketches so selected certain of the competitors, not more than six in number, to take part in the second competition, selecting those among them who in their judgment are best qualified by their professional training and experience to undertake so important a work. In order that they may make this selection with the fullest knowledge, these twelve competitors will be invited to send to the committee for their information a statement of whatever facts they may desire to bring to the committee's attention. The persons thus selected, and not more than six other persons or firms hereafter to be named by the trustees (or by the committee acting on the behalf of the trustees), will then be invited to take part in a second competition, which will be conducted under such conditions and in accordance with such instructions as the committee may then frame. The competitors in the second competition will be paid 800 dols. each, as the estimated cost to them of the drawings required. These drawings will be judged by a jury of seven persons, consisting of three members of the board of trustees, to be named by the board, the director and three practising architects, to be chosen by the competitors. This jury will, by a majority vote, select the designs, at least three in number, which they find to be on the whole the most meritorious, and will send them to the trustees, naming them in order of their merit, and adding such comments and criticisms as they may see fit to make. The trustees will send one of the designs thus submitted to the Board of Estimate and Apportionment for their approval, subject to such alterations and changes as may prove necessary or advisable, and will recommend the author as architect of the building. If the choice of the trustees should fall upon one of the architects chosen in the preliminary competition, the trustees reserve the right of association with him in the conduct and execution of the work, if they see fit so to do, some other architect to be agreed upon between him and them, and to divide the fees between these two, according to the division of the work and of the responsibility. The trustees may also, if they see fit, appoint an engineer to look after the work, to whom all drawings must be submitted for approval before they are carried into execution.

## ST. PAUL'S CATHEDRAL.—II.

**D**URING the present week no building in the world has been so much observed as St. Paul's Cathedral. Among the hundreds of thousands of people who have gazed at the outside it would be interesting to discover what percentage of them have realised the relation between the exterior and interior arrangements. To many it must have appeared as if the architect had anticipated the event of Tuesday and provided for it, although the authorities of the cathedral were unable to realise for so long a period the extent of the accommodation. The immense steps seemed to be prepared for the display of bishops and other ecclesiastical dignitaries, for civic authorities, for the representative men of the vast and scattered empire. The western gallery would have been more suitable for the performance of a purely ecclesiastical function, and WREN, when designing it, may have thought of one of the Roman galleries from whence the POPE bestows his blessing on Rome and the world; but on an occasion like the Jubilee commemoration, as on many others in England, the civil dare not be separated from the sacerdotal, and such a crowd of notabilities could not be arranged elsewhere than on the steps. The filling of the gallery with sightseers was undoubtedly a converting of what ought to be a religious ceremony into a spectacle, but we are afraid that in all ages the pleasure of the eyes has assumed more importance than the elevation of the soul. But on seeing how well the western part of St. Paul's lent itself to novel demands every Londoner must have felt more proud of his cathedral, and was more assured than ever about its being one of the few great marvels of architecture, and that its dome was the noblest in all the world and a type of the City.

The average citizen will not realise that the dome he looks on with so much pride from the streets, river or bridges is not the dome which meets his view whenever he attends service in the cathedral. Still less is he disposed to agree that there are not only two domes but three, for the cone and timber which give stability to the compound structure when gales sweep around St. Paul's is surely deserving of having a recognised existence. The exterior also generally gives the effect of a two-storey building; but where have the two vanished when we seek for them in the nave and aisles? St. Paul's is a scenic church, and foreign painters may have had a share in the preparation of the designs. We must, therefore, make allowance if occasional stage effects are borrowed in order to produce a sort of exaltation in the mind of the uninitiated spectator. If the cathedral could be considered as a building and no more, the differences between outside and inside might be condoned, but when writers like PUGIN assume St. Paul's to be a sort of symbol of doctrine, every deviation from constructional truth becomes an offence. WREN's straining after effect has created prejudices in the minds of some critics which are not justified. KUGLER, for example, who was acquainted with many architectural freaks, will hardly allow that St. Paul's deserves to be accepted as a church. He says it is "eines Gebäudes, dem es zwar an der höheren Würde des kirchlichen Charakters fehlt;" but anyone who was present at the impressive service of Sunday would not agree with that conclusion. When the mosaic decoration of the interior is completed the Christian character of the building will then be more manifest than at present.

If the sculptured decoration were alone considered, it must be allowed that WREN sanctioned much which would be equally in place in a secular building. With the exception of cherubs' heads, the sword assigned to St. PAUL and an occasional martyr's palm, the subjects of the ornament would not have appeared inapposite in a pagan temple. But it should be remembered that at the time the cathedral was erected there was as much fear of decoration that suggested Christian truths as if it carried contagion to all who looked on it. The sculptor or painter dare not attempt to assume a share in the minister's office by producing anything that would recall doctrine or history. Statuary and BIRD's relief in the pediment would probably never have been tolerated on the exterior if several vases were not set up near to suggest the standard which should be applied to them. In those days also architectural sculptors were not as abundant as they are now and such a man as GRINLING GIBBONS would be allowed to have his own way. His training was

not among ecclesiastical objects and he would feel he was to be commended for deriving so many elements from natural objects which were not tainted by heresy or superstition.

In creating a dual dome WREN was obeying an optical law. The eye is not satisfied when a convexity is turned into a concavity. The dome of St. Peter's, Rome, has more consistency than WREN's; but, however impressive is the interior, the outer appearance causes disappointment to all who see it for the first time. It cannot be said that the disappointment is a consequence of association, because we are accustomed to see spires on the outside of buildings, and a squat dome is therefore too much of a departure from precedent. The Italians and Romans are not familiar with the sight of spires, yet to them the dome of St. Peter's is not a perfect object. If we allow that the eye is to be gratified rather than the logical sense, WREN's treatment merits approval. It is true he conceals much, and he may be charged with artistic deception. But he could say he was only following nature's own precedents. "Things are not what they seem," and the latest, like the earliest, philosophy is based on the assumption that illusion is universal.

If judged by the principles of Mediæval construction, the screen forming the upper part of the side elevations is also factitious. Its main use is to conceal the buttresses which are needed to insure the stability of the vaults of the nave. If they are equivalents for the flying buttresses of Gothic buildings it is maintained they are too important to need any concealment. The same principle applies in this case with stronger force than in the case of the dome. If construction must be everywhere apparent, then the screen is unnecessary. WREN wished to suggest that his building was steadfast because of its weight and the proportion of its supports to the upper mass. Every part was, or should be, like a column, the weights falling along perpendicular lines to the foundations. The expression of a continuation of counter forces and resistances was to his mind, as to the ancients, inartistic, and he drew a veil over that part of his work where dynamics rather than statics were in operation. It is not improbable that WREN's work would have stood without so much buttressing, but he may have recollected how easily INIGO JONES's work was overturned because the piers were not erected so truly as the plans indicated. A letter, dated April 25, 1668, from JOHN EVELYN to WREN, suggests that in the seventeenth century the ablest masons could not be relied on:—

As they said of old *prudencia est quedam divinatio*, so science, at the height you are master of it, is prophetic too. What you whispered in my ear at your last coming hither is now come to pass. Our work at the west end of St. Paul's is fallen about our ears. Your quick eye discerned the walls and pillars gone off from their perpendiculars, and I believe other defects too, which are now exposed to every common observer. About a week since we being at work about the third pillar from the west end on the south side, which we had new cased with stone where it was most defective, almost up to the chapitre, a great weight falling from the high wall so disabled the vaulting of the side aisle that it threatened a sudden ruin so visibly that the workmen presently removed, and the next night the whole pillar fell and carried scaffolds and all to the very ground. This breach has discovered two great defects in Inigo Jones's work; one, that his new case of stone in the upper walls, massy as it is, was not set upon the upright of the pillars but upon the core of the groins of the vaulting; the other, that there were no keystones at all to tie it to the old work; and all this being very heavy with the Roman ornaments on the top of it; and being already so far gone outward, cannot possibly stand long. In fine, it is the opinion of all men that we can proceed no further at the west end. What we are to do next is the present deliberation, in which you are so absolutely and indispensably necessary to us that we can do nothing—resolve on nothing without you.

WREN may have thought there were contingencies which the keenest eyes could not discover, especially in a building so large where the foundations were laid with difficulty. He may also have suspected the loyalty of some of STRONG's mutinous masons. But to dispense with a screen and to allow the height of the aisles to be expressed by the exterior, although in keeping with many Italian examples, would have appeared undignified to WREN, who considered height was an indispensable element of grandeur.

In the exterior WREN could not expect to have

ancillaries in the form of altars, paintings, sculpture, &c., which not only in continental churches add to the effect, but often compensate for architectural defects. His building was to be deprived of colour, and must depend on its masonry. Accepting the restrictions WREN endeavoured to avoid monotony. He could have gained variety by the employment of columns and rounded surfaces, but although in the exterior of the building and of the dome WREN employed them with skill that must command admiration from captious critics, in the interior the squared pilaster is supreme. Some he fluted and cabled, others he left plain; he introduced panels wherever he could, and he coffered the greater arches. In all this we see an earnest endeavour to avoid monotonous surfaces, and his arrangements will hereafter enable a more effective system of decoration to be produced. The treatment of the archivolt over the arches which form part of the piers sustaining the cupola suggest that WREN had not sufficiently thought out the detail, and when the error was perceived it was too late for a remedy. All that could be done was to "fudge." That defect by itself is enough to suggest WREN's dependence on other men. But if we consider how inadequate was his training in the art of architecture, one must wonder the cathedral is not crowded with examples of the want of an exercise of foresight.

## A SHORT INTELLECTUAL HOLIDAY.

BY A CORRESPONDENT.

THE weary student, the jaded contractor, the clerk of the works—fagged out with the continual inspection of material, and sick at heart of being suspicious of every one's integrity—all these and many others hail with delight the prospect of rest and change. But where can that rest and change be found unassociated with vulgarity, frivolity and extravagance? Where can it be found associated with intellectual growth, change of scene and economy? These were the questions asked by the writer; the sequel will give the reply.

A holiday to be really enjoyable must meet the tastes of the holiday maker, it should make him physically and mentally more suitable for his daily toil, and it should not disturb his mind by its unflinching demands on the purse. The man who comes back to his work with his ideas enlarged, with broader views of humanity and with a keener love for the common tasks of life has certainly found the secret of a true holiday. The writer does not pretend to be the guide, philosopher and friend of the holiday-seeker, he simply desires to make known what he has himself experienced, and from which others through want of knowledge may shrink from attempting.

Take it for granted that the holiday merely extends from the Friday evening to the Wednesday morning after; let us see how much in that short time can be enjoyed, if the hours are but properly mapped out.

Friday evening finds us uttering a delightful "hurrah" as we hide away the implements of our constant labour; then, dressed in an easy travelling suit, with no more luggage than can be carried in our pockets or, at most, in a light hand-bag, and with a stout umbrella, we are soon seated in the train and hurrying along to Dover. As we mean to get rest in our holiday as well as pleasure, we study the guide-book and learn that Dover is so named from the river Dour, which runs through the town, and then prepare for a long night's rest, the enjoyment of which is another of the secrets of a successful holiday. We are out early in the morning, and are soon appreciating the bracing breeze on Shakespeare's Cliff, that

Cliff whose high and bending head  
Looks fearfully in the confined deep.

And here, with note-book in hand, we may certainly allow the imagination to run wild, picturing to ourselves scenes in English history familiar to every schoolboy; and if we possess but the mere outlines of the science of geology, the view of the white cliffs must awaken a train of thought into which such words as foraminifera, encrinite and spirifer will most certainly introduce themselves.

We have only time to pay a visit to the Castle heights, for our boat will start at noon for our trip across the

Channel. As we make our way to the Colton Gate we may, without doubt, believe that we are walking over the same road used by the Romans, the Thanes, the forces of Earl GODWIN and many others. Of the original fortress we can find nothing but the basement of a strong rubble rampart; Saxons and Normans had a share in this grand work, and placed as it is 375 feet above the level of the sea, it presents a defiant aspect to any future NAPOLEON who may contemplate its capture.

We glance at the many towers, examine the Roman Pharos, admire the ancient church of St. Mary-in-Castro, look at Queen ELIZABETH'S Pocket Pistol, cast at Utrecht in 1544, and presented to HENRY VIII. by CHARLES V., and having obtained all the information possible from our guide, we make ourselves comfortable on board the boat for our sixty miles trip across the Channel.

The boats of the Belgian Mail Packet Service are too well known to need description; the three hours' journey from Dover to Ostend on the *Henriette* or the *Josephine* can only be described by those who have enjoyed it by the term *par excellence*. The invigorating breezes of the Channel soon prove to us what restoration to a tired mind is to be found even in so short a journey. Safely landed at Ostend, we have only time to get some much-needed refreshment when we start on our seventy-five mile journey to the capital of Belgium.

The country is flat, but the green pastures abundant and ever refreshing. If this be our first visit, we shall find much to interest us. Our note-books will be constantly employed, for we have come to learn as well as to enjoy.

The evening finds us at Brussels. Having secured our room, and knowing, of course, by previous study of our "Baedeker," all the principal tram routes, we spend a couple of hours in tram rides through the city, and find that its general description of a miniature Paris is borne out by its wide boulevards, its magnificent shops, the grand cafés, and the general open-air life enjoyed by its inhabitants.

When we look out of our hotel window on Sunday morning, we shall be astonished to find so few indications of the ordinary repose of our English Sunday; but we have come for rest, and not for toilsome hurrying from place to place on an ordinary day of quietude. There are English churches at which we can feel quite as much at home as in our parish church, and surely we cannot spend our Sunday morning better than in peaceful worship.

There are many churches to visit, to miss which would be a pity. The ancient cathedral of St. Gudule must, of course, be inspected with care. We shall find it in the lower part of the town; it is erected on a slope; we approach it by ascending a flight of steps, and at once recognise it as an imposing Gothic church. The original church on this site was consecrated in 1047, the present church being commenced in the twelfth century; in the retro-choir we shall find some remains of the Transition style; the transept, the arcades of the nave and the south aisle are in Early Gothic and were completed in 1273, chapels were added from time to time and the whole restored between 1848 and 1856. We shall, however, remember St. Gudule more for its magnificent stained-glass windows dating from the thirteenth century, and the carved pulpit by VERLACGEN, which represents the expulsion of ADAM and EVE from the Garden of Eden. It is good to sit quietly in such a building as St. Gudule and let the mind wander for a time into other regions; no exercise gives the mind more perfect repose, and for a long time its influence casts a delightful halo over the most tiresome duties of life. There are many other churches to be visited, all of them having peculiarities described in the guide-books, so that we need not enter into details.

Monday is our day of serious business, for we have much to do; we must be out early in the morning to see the country people at the market and the milk carts drawn by dogs. Of course, our day's work is properly planned, so that we may not waste time. In the Rue Royale near the park gates we shall find the Palais du Roi; here pictures by RUBENS, VANDYKE and other great artists will attract our attention. Not far off is the Palais des Académies; from here we go to the Palais de la Nation, where the Chamber of Deputies holds its sittings. At the corner of the Place Royale is the Royal Library, containing 3,000,000 volumes, 60,000 engravings and 20,000 MSS. We may also visit the

National Picture Gallery and feast our eyes upon marvellous examples of paintings by TENIERS, RUBENS, VANDYKE and CUYP; the startling and extraordinary pictures in the Musée Wiertz will provide us subjects for many a dreamy night.

There are, however, two buildings to which we must pay special attention; they are the Hôtel de Ville and the Palais de Justice. The former is situated in one of the finest Mediæval squares to be found in Belgium; here in 1568 twenty-five nobles of the Netherlands were beheaded by order of the Duke of ALVA. The Hôtel de Ville will excite our attention by its highly decorated front, its banqueting hall of Gothic carved oak, the pictures in the waiting-hall representing scenes in the history of Brussels. If we have time to climb the spiral staircase, over 200 feet in height, we shall obtain a fine view of the surrounding country, extending even as far as the Field of Waterloo. As we leave the Hôtel de Ville we must not forget to go down a by-street to look at the celebrated Manikin Fountain.

The tram will now take us to the Palais de Justice. As we approach it we shall be astounded at its immense proportions; it is probably the largest building of modern days, and one smiles at the ambition of so small a State as Belgium that so large a building should be required in which to conduct its legal affairs. But a glance and the mind immediately thinks of the mighty structures of ancient Egypt and Assyria, and indeed POELAERT, who designed it, confessed that it was his object to adapt Assyrian forms to suit modern requirements.

Commenced in 1866, it was not inaugurated till 1883, the jubilee of Belgium's existence as a separate kingdom, and cost two millions of money. As we ascend one of the flights of steps leading to the vestibule we meet the colossal statues of DEMOSTHENES, LYCURGUS, CICERO and DOMITIUS ULPIAN. Constructed of Belgian granite, we see that the Græco-Roman style has been for the most part adopted; curved lines have been avoided, the porch having rectilinear terminations. Once in the waiting-hall, or Salle des Pas Perdus, we can conceive a little the immense size of the construction as we gaze up to the comparatively small dome 320 feet above our heads. We must not forget to look at the immense figures representing Justice, Law, Strength and Clemency. The number of rooms in this building astounds us—27 large court-rooms, 245 apartments for officials and 8 open courts. We have only time to examine a few. We find that great care has been bestowed in the selection of material, and great taste displayed in the decoration and furnishing.

The grandeur of this building can only be realised by those who have seen it, and who by personal inspection have been able to obtain some idea of its wonders; the view from the summit can never be effaced from the memory. As a matter of comparison it should be stated that the area of the Palais de Justice is 270,000 square feet, that of St. Peter's at Rome 212,000, St. Paul's 109,000.

Monday evening will find us congratulating ourselves, like LONGFELLOW's blacksmith, that

Something attempted, something done,  
Has earned a night's repose.

We shall be wise if we make it a long night, for Tuesday will bring us much to enjoy. We are early at the railway station, for we have an hour's ride to the city of Ghent. Here in the capital of East Flanders we fancy ourselves in Holland, for Ghent is a city of 26 islands, 270 bridges over canals, and still has its wall and its seven gates of entrance.

A delightful exercise at this spot would be to sit in the old square, the Marché du Vendredi, and there, gazing on the antiquated buildings, to consider the history of this remarkable town. Were there ever such warlike citizens? In 1297 they conquered a British army of 24,000 men under EDWARD I., for many years they maintained a vigorous resistance against the Dukes of BURGUNDY, whom they would not, till compelled, recognise as the Counts of FLANDERS; they showed the kings of Spain of what metal they were made; they erected belfries from which they might call the citizens to arms. We gaze upon the statue of JACQUES VON ARTEVELDE, their CROMWELL, and remember that though of noble family he became a brewer that he might be one of the people; in 1337 he was

Protector of Flanders, but he aroused the anger of the citizens when he proposed that EDWARD III. of England should be elected Count of FLANDERS, so that he was killed in his own house in 1345.

At Ghent we must visit the cathedral of St. Bavon, famous for the picture, *The Adoration of the Lamb*, by the Brothers VAN EYCK. We must examine the church of St. Pierre, said to have been founded in 610 on the site of a Temple of Mars.

It will be with feelings of regret that we find ourselves again at the station, and soon hurrying along for an hour and a half to the city of Bruges, the capital of West Flanders.

This we may call a dead city—in the thirteenth century the great mart of the Hanseatic League; but when the Archduke MAXIMILIAN drove the traders to England in 1488, Bruges declined, and England commenced her manufacturing superiority.

How rich is this city in Mediæval characteristics. At the cathedral, St. Sauveur, we may look upon works of art by JACOB VON OOST the Elder. At Notre-Dame we may see a small statue of the Virgin and Child by MICHEL ANGELO, truly a group of exquisite beauty. The Hospital of St. John, the Chapelle du Saint Sang, and the church of St. Jacques each have treasures on which to feast the mind.

We must not omit to visit the belfry tower, 353 feet in height; the climb of the 400 steps will be amply repaid by the view we shall behold, and also by the explanations we shall receive of the mechanical contrivance by which an enormous brass cylinder makes the forty-eight bells to send forth the most exquisite music, and caused LONGFELLOW to sing:—

In the ancient town of Bruges,  
In the quaint old Flemish city;  
As the evening shades descended,  
Low and loud and sweetly blended,  
Low at times, and loud at times,  
And changing like a poet's rhymes,  
Rang the beautiful wild chimes,  
From the belfry in the market  
Of the ancient town of Bruges.

Another hour in the train and we are again at Ostend, and once more ploughing the sea, for we have no time left to see anything but perhaps the outside of the celebrated Kursaal.

We are at St. Paul's before midnight, and back to our business on Wednesday morning, with our minds so refreshed, with such enlarged ideas of the world of art, that life after all is found to be worth the living.

## PROFITABLE EXTENSIONS OF ELECTRICITY SUPPLY STATIONS.

A PAPER was recently read at Niagara Falls, before the National Electric Light Association, by Mr. Arthur Wright, borough electrical engineer of Brighton, who has been the pioneer of the constant profit system as opposed to constant price for electricity.

The paper begins with a consideration of the question of extensions of plant, but it soon develops into a vindication of the Brighton system of charging, and an attack upon the others. In fact, the paper really is one upon cost of electrical energy, and is almost the same as the previous paper read before the Municipal Electrical Association.

Mr. Wright shows that the fact of a call upon a central station to extend its mains does not necessarily mean that the station is a commercial success. It will mean that the extension is a success if there is a profit derived from it, and the class of consumer tapped by the new mains will be a factor in determining the success or otherwise of the extension. Mr. Wright then goes on to say that there is an enormous field for extension amongst the small, long-hour consumer, and that this consumer is almost invariably a profitable one if he can be secured. To do so, electricity must be supplied at a price which will compete favourably with gas. The price cannot be reduced all round owing to the unprofitable customers becoming still more unprofitable, and in consequence a sliding scale is necessary.

For the domestic supply, price is of the greatest importance. The amount of electricity used is large per lamp; consequently the bills are serious if the price is high, and fortunately the very largeness of the consumption per lamp per annum allows the price to be brought down to a lower figure than gas, while the supply company can obtain a profit on its extension. Mr.

Wright further throws cold water on the efforts of engineers to increase their profits by the day load from motive power, while they leave the domestic lighting alone. He says:—"One would think, to judge from the load curves of many of the stations charging on the uniform-price system, that nine-tenths of the population went to bed about eight o'clock in the evening, yet an immense amount of light is required right on until eleven or twelve P.M., and being a prolongation of the load on the station can be dealt with under conditions most favourable to cheap supply. As a matter of fact, in such districts it will be found that consumers pay two lighting bills—one for electricity, which by reason of the high uniform price is only used for short-hour lamps in show places, and a second for gas or other illuminant which is used in the long-hour burners, yet the actual conditions under which these different lights are produced and supplied favour quite the reverse order of things. The public freely admit that electric lighting is necessary for living-rooms, offices, shops, theatres and restaurants, but with electrical energy at a uniform price, or other form of restricted tariff, they are apt to remain satisfied with gas in corridors, kitchens, bedrooms, &c."

The system proposed and used in Manchester, of charging a fixed sum per annum per lamp installed and a small price per unit, is also condemned, and the effect is shown to be an encouragement to people to use as few lights as possible, which means that the load connected is all of one kind and on at one time, it being to the consumer's disadvantage to install lamps which are seldom used, although they would probably be on at a different time from the other ones. The consequence is that the load factor is made worse. Also it is impossible in practice to get a correct idea of the number and size of lamps. The really most important objection is "the unwisdom and expense of, the domiciliary searches in private houses, hotels, &c., which this system requires. These visits are very objectionable to the consumers by reason of the intrusion upon the privacy of every part of the building; and from the company's point of view the expense entailed is considerable."

"In one way or another the public has tolerated a good deal from electrical men, but the author's own experience has led him to the conviction that the best policy is to give them a good and steady supply on an encouraging tariff and draw the revenues in due season, and otherwise to trouble them as little as possible." With this opinion we entirely agree and it would be well if managers of supply companies, and in fact all public companies, would take this to heart.

Another point which may be of interest is the condemnation of the system which charges less for power than light, irrespective of the amount of power and the time it is used. "For the *reductio ad absurdum* of this practice we have only to compare the relative profitableness of a basement user of lamps with that of an elevator motor. The former is the steadiest and longest consumer any manager can wish for, and the latter the most objectionable kind of short-hour user of electricity."

Then follows a most interesting portion of the paper referring to the great field in the displacement of private plants. The private plant is seldom laid down where the lamps are only used a short time per diem, as it would not pay; consequently a fair sliding scale would be the means of displacing the whole of the private plants. This point is discussed in a very able manner, and an extract may be of interest. "What is there fundamental in the organism of a central station which should enable it to furnish a block with electrical energy more favourably than can be done by means of an isolated plant? Clearly it is the diversity of the duty which may be performed by the central station. The costs of a plant supplying a few premises whose requirements make their individual load diagrams pretty closely coincide must clearly be higher than those of a station catering for a wide variety of demand. . . . This diversity of demand obviously entails a much smaller plant capacity than would be the case were all the lamps required for much the same purpose and at the same time."

In Brighton, since the adoption of the Wright system, many valuable private plants have been turned over to the supply mains, and not a single private plant has been put in.

This latter point should be of great interest to architects and those contemplating the use of a private plant, and they will do well to ascertain the system of charging from the supply mains before finally deciding on a private plant. There are many other very interesting points in this paper, but they are chiefly of interest to electrical engineers.

If the mission of Mr. Wright and others in advocating an equitable system of charging is a success, it is certain that electricity will become the cheapest light for the poor man, and that the rich will find it dearer than gas. This seems rather an extraordinary result, but on second thought it will be seen that it is the best possible arrangement and one which is eminently fair. The poor man requires, first of all, a cheap light and a healthy one; the rich one a light which will be artistic and pure, and which will not spoil his art treasures and decorations, and he does not mind what he pays for these qualities. Electricity sold under a tariff which gives a constant profit per unit sold for any purpose will conform to both these conditions,

and must therefore very soon displace gas in both classes of house. We wish Mr. Wright every success in his campaign against the constant price system, and soon hope to see electricity the light of all classes, from the sanitary aspect if no other.

### DELFT-WARE.\*

(Concluded from last week.)

THE preceding description relates to the process employed at Delft, the proportions being taken from Gerrit Paape. M. Deck states that in France the proportion of lead and tin in the calcine varied between three to one and four to one, and that the enamel consisted of calcine 44 parts, sand 44, sea-salt 8, soda 2, minium 2. These substances were mixed together and fused. He adds that the amount of calcine and sand were always equal, and that the fluxes alone varied, but within very restricted limits. Taking Gerrit Paape's proportions and reducing them to a common denominator of 100 for comparison with M. Deck's, we find as the composition of the Delft enamel, calcine 43½, sand 47½, sea-salt 6, soda 3. The constitution of the enamel is therefore nearly the same in both cases.

According to Piccolpasso the enamel of the Italian majolica of the sixteenth century consisted of a combination of the calcine, a frit called marzacotto, and sand. In the calcine the proportion of lead to tin varied between two to one and four to one. The marzacotto usually consisted of sand 12 parts, lees of wine 10, salt 3. The calcine, marzacotto and sand were fused in various proportions to form the enamel. Thus the marzacotto was of the same nature as the mastic, and contained the alkalies, but the proportion of sand was much less. A good deal of sand was therefore added independently, the proportions of calcine, marzacotto and sand being in two of the formulæ, 10, 10, 12 and 16, 10, 10. M. Deck states that in no other country but Italy and Holland were the alkalies introduced into the enamel by means of a frit. He considers this method preferable to that employed in France of fusing all the constituents of the enamel together at once, as the materials, being better incorporated, do not produce a saline efflorescence.

The glaze used at Delft (called the "Kwaart") was composed of mastic 36 parts, litharge of gold 42, potash 4, salt 7. These constituents were well mixed and fused, forming a substance of great hardness, which was then ground to an exceedingly fine powder. The litharge of gold is plumbic oxide, with a little minium. Replacing the mastic by its components, we see that the glaze may be regarded as composed of litharge 42, sand 30½, salt 10½, potash 4, soda 2. The Kwaart was, therefore, by no means a purely lead glaze, but was partly lead and partly alkaline.

Gerrit Paape gives the following two formulæ for the blue:—Zaffre 8, smalt 5, mastic 4; or zaffre 50, sand 25, potash 25. In both cases the composition was fused and ground to powder. A more common kind of blue was made by increasing the proportion of mastic or sand to the zaffre. On the other hand, the blue was improved by increasing the proportion of zaffre. The zaffre is a mixture of cobalt and sand; smalt is powdered glass coloured with cobalt.

Similarly for the violet there were two formulæ, according as the mastic was used or not, both of which are very simple, viz. "brownstone" 1, mastic 1; or "brownstone" 1, sand 2, potash 2. The "brownstone" was an ore of manganese. The formulæ for the yellow were: antimony 9, litharge of gold 7, calcine 1½, salt 1½; or antimony 10, litharge of gold 6, calcine 2, salt 3. Gerrit Paape states that the red was obtained by burning good bole five or six times. The bole was a clay coloured by oxide of iron.

There were no other colours; green was obtained by mixing yellow and blue, and orange by mixing red and yellow.

The fact that both the Italians and the Dutch introduced the alkalies into the enamel by means of a special frit, and that in both countries the ware was covered with a glaze, which was partly plumbic and partly alkaline, affords strong evidence that the Dutch must have derived their method of fabrication directly from the Italians, and it would seem to establish a closer connection in this respect between Italy and Holland than between Italy and any other country.

Now that the "mystery of porcelain" has long since passed away and that it is certain that hard porcelain will continue to be manufactured for years to come in great and possibly increasing quantities, it would seem that the relative positions of porcelain and faience have become inverted since the first half of the last century. Faience belongs, as an industrial product, to a past stage in the world's history and it is unlikely that delft-ware will ever be made again commercially on an extensive scale for practical use. There may be artistic revivals, but it is clear that for domestic purposes (dinner services, &c.) the fragile and clumsy faience cannot compete with stone

\* A paper by J. W. L. Glaisher, Sc.D., F.R.S., read before the Applied Art Section of the Society of Arts.

wares and porcelains.\* We have seen that in the manufacture of delft-ware the nature of the surface called into existence a special kind of rapid painting—a distinct art, which was capable of producing unique results of great merit. We may feel pretty sure that if artistic work of a high character is again produced upon a stanniferous enamel under a lead-alkaline glaze, it will be essentially different from the fabrics of the old Delft potter.

In the last few years the old delft-ware has been copied in immense profusion, not only the forms and designs, but often the makers' marks being reproduced.† The surface and colours, however, are so dull that no one who has made any study of the subject could be deceived. It seems probable that the difference may be partly due to the fact that in the modern copies some mode of painting on a hardened surface is adopted. Judging by the vast amount of modern "blue and white" delft-ware exhibited in the shops of all the countries in Europe, the amount placed upon the market must have been enormous.

It is singular that there should be, apparently, so great a sale for these modern goods, which are high-priced and wanting in the very qualities which gave to the old delft its chief attractiveness; and it is also curious that the new wares should not cause greater attention to be paid to the old, but, so far as I can see, the flooding the shops with the reproductions and forgeries seems to have made no difference to the collector; of course prices have risen, but this is probably merely as a consequence of the generally increased interest which is being taken in all kinds of antique works of art.

At the old factory of "The Porcelain Bottle," at Delft, an excellent and interesting ware is now made by MM. Thooft & Labouchere, but it is quite different in character from the ancient products of the town, the body being white and hard. This factory has never ceased to exist, though for a time, after the extinction of the old trade of the town, M. Thooft used it merely for the manufacture of fire-bricks, &c.

It is greatly to be regretted that delft-ware should be so poorly represented in ceramic collections. In the continental museums Holland has almost as much ground for complaint as England with respect to the kind of specimens exhibited. There are small but interesting collections of Dutch delft at the Cluny Museum in Paris, at Sèvres, and a few other places, and valuable local collections are to be found in the museums of Nuremberg, Boulogne and very many other towns. But, as a rule, the specimens of Dutch delft exhibited consist of pieces of the commonest order, which give an unjust and misleading idea of the character of the ware. The only representative collection which I know of that contained in the Rijks Museum at Amsterdam. Next in order of value I should be inclined to place the collection at South Kensington, as though the pieces are few in number they are as a rule beautiful of their kind, and well display the merits of the ware. Moreover, they are of the class which a collector has but little chance of obtaining for himself, except on the dispersal of one of the great private collections.

Everyone who is interested in delft-ware must feel himself under the deepest obligation to M. Havard for his splendid work, which has made it possible, for the first time, to study the subject with the help of accurate historical knowledge. Not only has M. Havard searched all the known documents relating to the town and the guild, but he has minutely examined the register of the two churches—the Oude Kerk and the Nieuwe Kerk—at Delft, and extracted all the references to any person whose description showed any connection with pottery. He has thus brought to light and classified a great mass of authentic facts and dates respecting the faience-makers of the

town, which is quite independent of any knowledge derived from the wares themselves.

Before M. Havard had laid down the lines of the subject, and placed at our disposal this invaluable body of unimpeachable evidence, all that was known of the history of the manufacture consisted of some references contained in contemporary works, of a few names, marks and dates, extracted from the records of the guild, and of a certain number of other marks, which had been identified, some on very questionable grounds, and, as we know now, quite erroneously.

All this has been changed, and the student of the ware, having M. Havard's framework on which he can perfectly rely, and being assured of the main facts of the history, is enabled to group his pieces according to their date and maker, with some approach to certainty, and instead of wandering aimlessly among a wilderness of marks, he has it in his power to supplement the documentary evidence by useful additions to the history of the fabrication.

M. Havard's list, though it contains no less than 763 delft ceramists, is necessarily very far from exhaustive; for example, it is not possible to derive from it a complete succession of proprietors of any one factory, the dates showing at once that there must be numerous gaps. The collector may therefore perform a useful service by noting the existence of a factory mark occurring with new initials, and indeed, by placing on record any initials or makers' marks occurring upon any piece presumably made at Delft, and which are not identifiable by means of M. Havard's data. No doubt the principal delight of the collector is derived from the contemplation of the objects themselves, associated as they are with artistic or technical or archaeological interest, but it is always extremely unsatisfactory when he has to be content with this personal pleasure, and is debarred from the means of contributing to the literature or history of a subject in which he takes a real interest.

I think that any connoisseur in delft would always do well to make a serious study of the wares actually made in Delft—treating them as the standard or criterion with which all other wares made elsewhere were to be compared—whatever further investigations he might make with respect to the products of other localities. M. Havard has provided him with an admirable guide, which is not only a history but a mine of facts, from which he may deduce much additional knowledge for himself. The old town of Delft is so little altered from the time when its canals were filled with barges laden with the wares just carried across the quays from the factories (which were all in the town) that it is very easy as one walks through the quiet streets to-day to picture the scene when the trade was at the height of its prosperity. M. Havard gives the position of the factories and the place of abode of the potters, as extracted from the books and registers, and there is scarcely a street or lane that is not associated with a name or a factory familiar to the collector or connoisseur.

It would be quite unpracticable, I believe, for any one person to attempt a detailed study of delft-ware as a whole, so numerous and widely scattered were the places at which it was made.\* At whatever part of Europe one is staying there is always ample scope for research in the collection and examination of the delft-wares which have been in use in the vicinity. Leaving out of consideration the objects obtained for their quality or artistic excellence, and having regard only to those of antiquarian interest, the collector would probably find it most profitable to restrict himself to the products of a single country or a few localities, and to harden his heart to the delft-wares of minor factories of other places, unless they were remarkable in themselves, or helped to illustrate certain points.

It is natural in England to pay special attention to the English delft-wares, although, as has been pointed out by Mr. Solon, not being original products of the country, they necessarily present less interest than the purely English ceramic work of the seventeenth and eighteenth centuries. Still they afford a very attractive and untouched field for investigation, and offer many curious problems for solution.

Taking, for example, the so-called Staffordshire delft dishes, generally ornamented with blue dashes on the border, and painted in the middle with representations of Adam and Eve, King William, William and Mary, &c., why were they of this particular form, why are they without enamel on the back, when

\* In 1789 there were in France no less than 165 manufactories of faience and porcelain (exclusive of mere potteries) established in seventy-four towns. Rouen had 16 factories and was followed by Paris 14, Nevers 12, Marseilles 11, Bordeaux 8 and Meusiers 5. This list of places and number of factories is attached to a protest from the French makers of faience and porcelain to the National Assembly against the treaty of commerce with England (*Champfleury, Histoire des Faïences patriotiques*, third edition, Paris 1875, p. 376). Even if we suppose that France possessed more than its natural proportion of faience-makers, these figures suffice to show how numerous must have been the localities at which delft-ware was made in Europe. It is not unlikely that there were many more English factories than has been supposed, and that some existed in parts of the country which have not hitherto been regarded as probable ceramic centres.

\* The fragile nature of delft-ware is well illustrated by the great scarcity of articles intended for domestic use, excepting only plates and punch-bowls. I have in my collection but one wash-hand basin and one teapot. Teacups are excessively rare, although they must have been made in great numbers. It is curious, however, to note that delft-ware jugs are still made in France for ordinary domestic use. Last year at a crockery shop in Caen I bought a small white jug (not unlike Lambeth delft) which was stamped with the name of its factory, Lunéville, and I have bought at similar shops in Dieppe and Rouen modern delft jugs (possibly also made at Lunéville) with a white decoration upon a blue enamel, exactly similar to the jugs occasionally met with in England and believed to have been made in Staffordshire during the last century in imitation of the blue ware of Nevers.

† Some of the modern so-called "delft" is very far from being a reproduction of the old ware; the shape and perhaps general style of design are followed, but the treatment is different, and the pieces bear the mark of their (modern) factory. In many cases, however, the old pieces are exactly copied, and also the mark of an old Delft potter or factory or both, without the addition of any modern mark. These objects are constantly labelled in shops "fine old delft," and presumably they were intended to be sold as such. It should be mentioned that the coloured ware of Rouen has also been reproduced very successfully in great quantities; and reference should be made to the faience produced at Quimper, which is properly marked, and may be regarded rather as a development than as a reproduction of the old wares of the town.

were they manufactured, and over what period do they extend? I have never seen any Dutch pieces of the same class, and, in fact, they suggest Italy and not Holland. On comparing a number of specimens, the body of the ware is seen to exhibit so many marked differences that it is evident that these dishes must have been produced in several, and probably in a good many, distinct localities, although no actual places of manufacture can be suggested at present with any show of evidence except Lambeth and Staffordshire.\* The limits of date are probably from about 1640 to 1750, but nothing is known or has been conjectured so far as I know with respect to the origin of these pieces, either as regards shape or decoration. A collector continually meets with curious and puzzling specimens, but it may safely be said that there are no more interesting or mysterious groups of objects in English ceramic history than these early enamelled earthenwares. But however suggestive the existing specimens of this rough ware may be, it is not likely that anything very definite can ever be ascertained except from documentary evidence or excavations on the site of old potteries.

The course of the development of English delft is peculiarly interesting from several points of view, but especially in connection with the efforts which were being continually made by the delft-potter to imitate in his more cumbrous ware the shapes and styles of the porcelain of Chelsea, of the perforated ware of Leeds, &c. The same attempt at rivalry is apparent also in respect to the transfer-printed designs on stoneware, and I possess a delft plate with a hand-painted attempt at the willow pattern. The reproduction of the styles and designs of Dresden, &c., took place also on the Continent, but the contest between the cheaper delft and the finer English wares that were to supplant it is more noticeable in this country, and some of the efforts of Delft to rival the contemporary porcelain or stoneware form curious records of a struggle to which there could be but one end.

#### YORKSHIRE ARCHÆOLOGICAL SOCIETY.

THE members of the Yorkshire Archæological Society held their biennial excursion on the 18th inst. Markenfield Hall and Ripon Minster were visited by about seventy members and a large number of ladies. At the Ripon railway station the party was met by half a dozen waggonettes, in which they drove direct to Markenfield Hall, which, with one or two unimportant alterations, stands precisely as it did at the beginning of the fourteenth century. Indeed, Markenfield Hall is the finest example of a thirteenth or fourteenth-century manor-house in the northern counties. In the hall, the hon. secretary, Mr. William Brown, of Trenholme, Northallerton, gave a brief and interesting sketch of Markenfield Hall and its owners. The earliest mention of the house appears to have been in Domesday Book. Not until early in the thirteenth century did it come into the possession of the Markenfield family. In 1316 the then owner and founder of the family fortified it, digging around it the moat which still re-

mains. From this date until the reign of Queen Elizabeth the owners seem to have lived peacefully at Markenfield, the eldest sons going up to Oxford, and returning to succeed uninterruptedly to the family estate. It appears, however, that trustees were not always unimpeachable even in Mediæval days. One for breach of trusteeship was actually excommunicated; he was imprudent enough to tamper with trust funds left by a churchman. A Markenfield was concerned in a rising against Queen Elizabeth, for which he was attainted, and fled to France. On his death the attainder was reversed, and the old hall remained in the possession of his descendants until the last century, when it was bought by an ancestor of the present owner, Lord Grantley, who was Lord Chief Justice of the Common Pleas. The ancient chapel and the solar (or Lord's retiring-room) were visited, and, despite the rain, many of the guests climbed the winding stairs leading to the roof and peeped through the cross-bow embrasures at the surrounding country. The old buttery in the basement, which remains just the same as in 1300, was also worth a visit. During the stay at the Hall, Mr. C. C. Hodges, of Hexham, competent authority, described the architectural features of the building. After a hearty vote of thanks to Mr. and Mrs. Foster, Ripon Minster was visited, the Society being received by the Dean (the Hon. W. H. Fremantle) who kindly gave an interesting sketch of the building. Mr. Hodges described its architectural features and the visitors then explored the Minster, inspected the mural tablets and effigies, the carving of the stalls of the canons and admired the beautiful east and west windows. The Anglo-Saxon crypt, sole relic of the church built by St. Wilfrid, was inspected, being lit for the nonce by candles, that the narrow steps, worn by the feet of countless penitents, might not be responsible for any accidents. The Norman crypt, constructed with the main body of the church by Roger, the great building Archbishop of York (1154-81), was likewise visited. After a stay of an hour and a half in the Minster, a move was made to the chapel of the Hospital of St. Mary Magdalen. This building, which is now disused, is one of the most venerable in Ripon. It owes its erection to Thurstan, an Archbishop of York, and amongst the objects of interest may be mentioned a fine old oak Perpendicular chancel screen and an ancient plate chest. With this visit ended the excursion to Ripon, and while general regret was felt and expressed that the weather had been so unpropitious, the opinion was shared by one and all that the day had been by no means unpleasantly or unprofitably spent.

#### EDINBURGH ARCHITECTURAL ASSOCIATION.

THE Edinburgh Architectural Association, on the occasion of its annual excursion on Saturday, visited Linlithgow. Mr. Thomas Ross, president of the Association, conducted the party over the Palace in the unavoidable absence of Mr. W. W. Robertson, and described the plan and the manner and periods of the erection, and drew attention to the means which have been taken by Her Majesty's Board of Works to preserve the building from further decay. Mr. John Honeyman, R.S.A., architect for the restoration of St. Michael's Church, described the condition of the church before the work of restoration was begun, pointed out what had been done, and showed on drawings the proposed additional work. After luncheon at the Star and Garter Hotel, the President read letters of apology for absence from Provost Gilmour, Mr. W. W. Robertson and Mr. T. Fairbairn. Dr. Rowand Anderson moved a vote of thanks to Mr. Honeyman for the interesting description of the restoration of St. Michael's Church, and expressed the appreciation of the members of the Association for the manner in which the work had been carried out. Mr. W. Horn Henderson, Linlithgow, moved a vote of thanks to Mr. Ross for his explanatory description of the Palace, and Mr. Honeyman and Mr. Ross having replied, the President said it would be an unpardonable omission if the Association allowed this visit to the royal and ancient burgh, so long and intimately connected with the kings and queens of Scotland, to pass without one toast—that of Her Majesty the Queen. The toast having been duly honoured, the party drove to Bonhard House and Kinneil House, which were carefully examined under the leadership of Mr. Ross, who drew attention to the fine plaster ceilings at the former, and described the erection of the latter as two houses joined together by wings in the reign of Charles II. An examination was also made of the ruins of a chapel at Kinneil, which is being carefully cleared under the direction of Mr. Macaulay, factor for the Duke of Hamilton, of the rubbish which has accumulated over the foundations.

The Alexander II. Bridge, the foundation-stone of which was laid by the Czar during his visit to Paris, will, owing to the cost, be reduced in width from 60 to 40 metres, and instead of the decorative work being done in marble, ordinary stone will be used.

\* Attention has been drawn to the fact that the subjects represented on these dishes are so few in number, "Adam and Eve" being the only scriptural design; but I do not think that it has been noticed, except by Mr. Downman in his *English Pottery and Porcelain*, published last year, that floral decorations, generally tulips, and fruit (grapes and apples) and leaves also occur. The "Adam and Eve" is much the most common of the designs, but the floral and fruit patterns are not infrequently met with, at all events in the eastern counties. I have myself eight or nine specimens, and there are nearly as many more in the Saffron Walden Museum. It is to be noticed, however, that the dishes with kings and queens are well known, and have been figured in Church's *English Earthenware*, and Solon's *Art of the Old English Potter*, so that a good many of the existing specimens have already found their places in museums and collections. Several of the tulip designs are very effective and well coloured, but on some of the dishes the colouring is extremely bad and even painful. It is noticeable that green is much more freely used than in the contemporary Dutch work; sometimes it is very good, suggesting the green of Brussels delft, but it is often muddy. The red seems to have been painted above the glaze with a kind of dissolved sealing-wax. This method of applying the red was employed on other pieces of Early English delft, and I have specimens in which it has all been worn off except a few specks which just serve to show that it once existed. I believe that many early pieces which now show no trace of red were originally painted in this way. Returning to the "blue-dash" dishes, I may mention that several of mine have been obtained directly from cottages and small farmhouses, and that they seem to have been always used for mere decoration. I have long suspected, what Mr. Downman has suggested, that there must have been a very early delft factory on the eastern side of the country. These dishes show on their fronts the marks of the three spurs by which the dish above was supported during the firing, the flange of one dish resting upon spurs placed in the one below. In other kinds of English delft-ware the plates and dishes were supported from underneath the edge by three projections from the side of the seggar, as in the case of the Dutch wares.

## NOTES AND COMMENTS.

THE council of the Architects' Benevolent Society are able to announce that its progress was maintained during the past year. But the sum received is still inadequate to the applications for assistance. Last year's subscriptions amounted to 460*l.* 15*s.*, while the sum expended on grants was 604*l.* 15*s.*, exclusive of 70*l.* dispensed in pensions. As at the beginning of the year there was a balance to the credit of the capital account of 117*l.* 15*s.* 8*d.*, and during the year the sum of 333*l.* 12*s.* was received in donations, it was, therefore, thought well to increase the investments of the Society by the purchase of 250*l.* Caledonian Railway 4 per cent. debenture stock, at a cost of 386*l.* 17*s.* 6*d.*, thus leaving a balance in the hands of the bankers on December 31 of 64*l.* 10*s.* 2*d.* This purchase increases the value of the Society's holdings of stock to (at cost) 9,893*l.* 0*s.* 4*d.*, which, with the balance at the bankers, leaves the total capital at 9,957*l.* 10*s.* 6*d.* Successive councils who have administered the affairs of the Society have for many years made efforts to increase the capital of the Society to 10,000*l.*, and it is a matter of satisfaction that the investments have now practically attained this point of stability, their value, indeed, at market quotations being in excess of this sum. Architectural practice does not tend to foster benevolence, for it is a constant fight in which everyone must rely on himself alone. But as in modern warfare succour is not withheld from a wounded enemy, so it is not generous to look on every broken-down architect as a possible rival and to leave him in distress. For a profession which counts so many members 460*l.* is not a creditable offering, especially when it is known that architects, unlike painters and actors, cannot rely on the generosity of the public.

IF architects have not shared in the Jubilee honours, they have at least the satisfaction of knowing that the two representatives of art selected for knighthood are to some extent connected with architecture. The reputation of Mr. WYKE BAYLISS has been gained by representing buildings, and especially by interior views. Paintings and drawings prove that he is not an artist who gives little time to the selection of a point of view. Nor does he depend for his detail on photographs. He endeavours to discover what is most impressive and characteristic in a building. If his success has not been equal to his merits that may be owing to his prominence in the unlucky Society of British Artists. Mr. WYKE BAYLISS has been the most loyal of presidents, and has endeavoured to keep the discordant elements together, but we are afraid he has had to pay for his solicitude. Mr. W. B. RICHMOND, R.A., is known by his mosaics in St. Paul's Cathedral, but he has painted portraits and has modelled one statue. He has also held a Slade professorship. The two knights are competent artists, but on such an occasion some of the survivors of the artists of 1837 would appear to be more fitting representatives, viz. Mr. HOOK, Mr. HORSLEY or Mr. COOPER.

ATTACHED to the American Navy is a Civil Engineers corps. Although the property under their control is valued at 50,000,000 dols., and new architectural and engineering works have to be undertaken every year, there are only twelve members of the corps. As one of them has retired, a new appointment will have to be made after a competitive examination. Americans between twenty-five and thirty-five years are eligible. Each candidate must produce evidence of having pursued a course of civil engineering at some professional institution of good repute, and of having had at least two years' practical experience as a civil engineer. Candidates who pass a satisfactory examination will be arranged by the board in the order of their relative merit. Examinations will be in writing. Candidates will be examined in the following subjects:—English grammar and composition, elementary physics, elementary geology, drawing, arithmetic, general knowledge of algebra, geometry, trigonometry, analytical geometry, differential and integral calculus. Also applied mathematics, including mechanics of solids and fluids and strains in structures, constructional materials, engineering constructions including workshops, chimneys, quay walls, wharves, dry docks, sewers, yard railways, pavements, water distribution, foundations, &c., surveying, topographical, trigonometrical and hydrographical,

and mapping same; instruments, their use and adjustments.

MANY documents in architects, surveyors and contractors' offices have to be carefully conserved, for years after their preparation they may become important evidence. Care should be taken that they are drawn or written on paper which can endure. A Cantor lecture by Mr. C. F. CROSS reveals that many modern varieties of the material that is called paper are most fleeting. He describes a valuable set of actuaries' tables which after a year or two of office use was in such a condition that it had to be mounted with varnish, leaf by leaf, upon cloth, at a cost of 3*l.* 10*s.* Apparently the transactions of societies have the least chance of any printed matter of a survival, for the paper employed is selected on account of its showy appearance, which is merely superficial, and when it loses its lustre, what is printed on it vanishes. The Germans, who are giving attention to the subject, lately analysed ninety-seven standard publications from various countries. Only four were found to have less than 5 per cent. mineral stuff, and sixty-two were composed of inferior stuff and mechanical wood. It is known that drawing papers have become liable to attacks of micro-organisms. One of the causes is the employment of gelatine as a sizing agent. When the papers become moist, as happens when colour is applied, bacterial life is stimulated and rapid growth follows. It is proposed as a remedy to add antiseptics to the size, but they bring disadvantages of another sort. It may be assumed that the deterioration of water-colour drawings is as often produced by the use of paper containing unsafe materials as by inferior colours.

THE Dean of St. Paul's has utilised the commemoration festival as an opportunity to plead for funds, which will enable the authorities to continue the adornment of the cathedral with mosaics. Through the liberality of four City companies the half domes at the corners of the great dome will be filled with mosaics before the end of the year. This and other work that is in progress will exhaust the funds at the disposal of the Dean and Chapter. They are very anxious to carry on what has been so well begun whilst they can have the invaluable help of Mr. or rather Sir W. B. RICHMOND. There are two parts which are pressing. One is the space between the whispering gallery and the bottom of the windows in the dome. To cover this with mosaics will cost not less than 10,000*l.* The other is to decorate the roof of the aisles of the choir, where there are six small shallow domes, with a place for the arms of any donor who would kindly give 1,000*l.* for the completion of one of them. The authorities are anxious to make arrangements with the artist so that there may be no stoppage in the work. The money will not be wanted until next year, and therefore a promise to be fulfilled next year would suffice. Unless there is a certainty that the money will be forthcoming the Dean and Chapter cannot undertake the risk of continuing the mosaic decoration.

It is occasionally said that the best time to advocate costly building projects is when engagements are entered into for the execution of similar undertakings. M. CHARLES NORMAND, who is known to all Paris as the president of the Société des Amis des Monuments, as well as by his architectural works, is evidently of that opinion. He wants the French Government to rebuild the Tuileries. M. NORMAND does not mean a rebuilding of a similar character to the old historic buildings which so often figure in the grounds of exhibitions, but a reproduction which will be at least as costly as the original, though the money will be measured by a different standard. There is a necessity for the restoration, as at present the garden with its statues is an inadequate substitute for the building in which PHILBERT DE L'ORME, JEAN BULLANT and DU CERCEAU co-operated. Paris wants a palace for imperial and royal visitors, and the new Tuileries would serve that purpose.

## SIR C. WREN'S BUILDINGS.

THE cathedral of St. Paul is the most important of Sir Christopher Wren's buildings, and by itself is enough to insure his reputation as an architect. But he designed many other buildings. The most complete list of them was prepared by James Elmes, and is as follows. With very few exceptions the date only of the finishing of each building is given:—

1. Sir Christopher Wren's first architectural appointment was that of deputy surveyor-general of the Royal Works and Buildings in September 1661, and his first works the reparation of old St. Paul's, the restoration of Windsor Castle and the King's new palace at Greenwich, &c.

2. [1663] Fitted up the choir of old St. Paul's for divine service, and designed the new fortifications of Tangier, which had been given to Charles II. as part of the dower of Catherine, Infanta of Portugal, whom he had recently married.

3. [1663] Made plans, elevations and sections of old St. Paul's for the purpose of the proposed alterations and repairs. He also began the Sheldonian Theatre, which will be enumerated when finished, and is only mentioned as being his first executed building.

4. [1663] The chapel of Pembroke College, Cambridge, built at the sole cost of his uncle, Bishop Wren.

[1666] The great fire of London.

5. [1666] Made a design and laid it before Parliament for rebuilding the City of London, and a detailed estimate of the damage sustained, which amounted to 10,780,500*l.* He was appointed this year architect to St. Paul's and for rebuilding the whole city.

6. [1666] Fitted up a portion of the old cathedral for divine service.

7. [1668] Finished the Sheldonian Theatre, Oxford, which was opened with much ceremony in the following year.

8. [1669] Reported on the state of St. Paul's Cathedral.

9. [1669] The new Royal Exchange opened by Sir William Turner, the Lord Mayor and the Gresham committee, ninety-nine years after its opening by Queen Elizabeth.

10. [1672] Temple Bar finished.

11. [1677] The Doric column, commemorative of the fire of London, finished.

12. [1677] The parish church of St. Mary-le-Bow, in Cheapside, and its fine steeple finished.

13. [1677] Finished the chapel of Emanuel College, under the auspices of Archbishop Sancroft.

14. [1678] Finished the Custom House, London.

15. [1678] Restored and enlarged the parish church of St. Mary-at-Hill, Tower Street, called in ancient records "St. Maria ad Montem," to suit the purpose of the united parishes of St. Mary-at-Hill and St. Andrew Hubbard, the latter church having been destroyed, whilst the walls and ancient tower of the former were not much injured.

16. [1679] The parish church of St. Michael-on-Cornhill, to which the lofty tower, a humble imitation of that at Magdalen College, Oxford, was added, from Wren's designs, in 1722.

17. [1679] The parish church of St. Olave Jewry, on the western side of the street called the Old Jewry, finished about this time.

18. [1679] The beautiful little elliptical church of St. Benedict or Bene't Fink, Threadneedle Street, a free imitation of the twin churches by the Piazza del Popolo, Rome. It was taken down after the rebuilding of the present Royal Exchange, to make room for the row of houses on its eastern side, which reach from Threadneedle Street to Cornhill.

19. [1679] About this time he finished the parish church of St. Dionis-back-church, in Fenchurch Street and Lime Street, and added the tower and steeple in 1684.

20. [1679] Also the parish church of St. George Botolph, on the western side of Botolph Lane, near Billingsgate.

21. [1679] The parish church of St. Sepulchre, opposite the north end of the Old Bailey, about this time; the tower is the ancient one repaired.

22. [1679] Flamsteed House finished about this time.

23. [1680] The parish church of St. Magnus, London Bridge, to which he added the tower and spire in 1705.

24. [1680] The parish church of St. Mildred, in the Poultry.

25. [1680] About this time the parish church of St. Stephen, Coleman Street.

26. [1680] The parish church of St. Lawrence Jewry, at the corner of Gresham Street and Guildhall Yard. In this church lie the remains of Archbishop Tillotson.

27. [1680] About this time also the parish church of St. Mary, Aldermanbury, and also

28. [1680] That of St. Nicholas, Cole Abbey, on the south side of Fish Street, Doctors' Commons.

28. [1680 or rather earlier] Repaired that of St. Mary-Woolnoth, Lombard Street, which was afterwards rebuilt on a larger scale, to serve two parishes, in 1719, by Nicholas Hawksmoor, a worthy pupil of Wren, in a singularly bold, solid and original style.

29. [1680] Also the parish church of St. Michael-le-Quern,

Queenhithe, formerly Quern or Cornhithe, Upper Thames Street.

30. [1681] Design, estimate, &c., for a mausoleum for Charles I. The House of Commons voted 70,000*l.* for the expense.

31. [1680] Designed the pedestal and superintended the erection of Le Sueur's fine equestrian statue of Charles I. at Charing Cross.

32. [1680] The parish church of St. Michael, Bassishaw, or Basinghall Street, so named after an opulent mercantile family of that name which resided there.

33. [1680] The parish church of St. Swithin, London Stone, Cannon Street, the interior and construction of which are worthy the attention of the architectural student. It was repaired in or about the year 1826. The London Stone, enshrined in a stone case, is the remains of the ancient Roman miliarium, from which the distances from the Metropolis were measured, and upon which the rebel, Jack Cade, laid his sword, when he proclaimed himself King of England in the reign of Richard II.

34. [1680] The parish church of St. Bartholomew, in Threadneedle Street, except its ancient tower. It was taken down to enlarge the area round the Royal Exchange, and its site occupied by the Sun Fire and Life Assurance Office.

35. [1681] The parish church of St. Stephen, Walbrook.

36. [1681] The parish church and its fine but now diminished spire of St. Bridget or St. Bride, Fleet Street, which was further embellished by its architect in 1699.

37. [1681] The church and incomparable steeple of St. Mary-le-Bow, Cheapside.

38. [1681] The parish church of St. Clement Dane, in the Strand, to which the present tower and steeple were added in 1719, by James Gibbs, the architect of the churches of St. Mary-le-Strand, St. Martin-in-the-Fields, the Ratcliffe Library, Oxford, &c.

39. [1681] The parish church of St. Anne and St. Agnes, in St. Anne's Lane, at the northern end of the General Post Office, St. Martin's-le-Grand.

40. [1681] Rebuilding the part of the Temple destroyed by the great fire.

41. [1682] The parish church of St. Peter, on Cornhill.

42. [1682] The parish church of St. Antholin, Watling Street.

43. [1683 *et seq.*] The episcopal palace, Winchester, for and at the sole expense of Bishop Morley.

43. [1683] The royal palace at Winchester, for Charles II.

44. [1683] The parish church of St. Allhallows the Great, Upper Thames Street, near the Steel Yard,

45. [1683] The Ashmolean Museum, Oxford.

46. [1683] The parish church and tower of St. Augustin and St. Faith; the elegant spire, which has been spoiled by some modern Goths, was added in 1699. The united parishes being unable to agree upon an architect to superintend the reparation of Wren's work, each employed their own "Surveyor;" one whitewashed the interior and the other ruined the spire.

47. [1683] The parish church of St. Bene't, Paul's Wharf, on the north side of Upper Thames Street, and near to its western end. This parish is distinguished as the birth and burying-place of Inigo Jones.

48. [1683] The parish church of St. James, Westminster, situated between Piccadilly and Jermyn Street, built at the expense of Henry Jermyn, Earl of St. Albans, and other of the principal inhabitants of that district, which was before that time a precinct of St. Martin-in-the-Fields, and made parochial by Act of Parliament, the third, James II.

49. [1683] The parish church of St. Mildred, Bread Street, was also finished this year. In this parish John Milton was born, which event is commemorated on a tablet outside the church.

50. [1684] The entrance and frontispiece to the Inner Temple was began this year and finished, according to the inscription, in 1688.

51. [1684] The church of the united parishes of St. Allhallows and St. John the Evangelist, Bread Street.

51. [1684] The parish church of St. Martin, Ludgate, on the north side of Ludgate Hill, just inside the side whereon stood Lud Gate, in the western wall of the original City of London.

52. [1684] The chapter-house of the Dean and Chapter of St. Paul's.

53. [1685] Finished the parish church of St. Alban, on the east side of Wood Street, Cheapside; an indifferent attempt, as far as style, of the ancient Pointed mode.

54. [1685] The handsome, capacious and conspicuous parish church of St. Bene't Gracechurch, at the corner of Fenchurch Street and Gracechurch Street. The interior is a double cube of 60 feet by 30.

55. [1685] Archbishop Tennison's Library, near St. Martin's Lane, Westminster, in conjunction with his friend John Evelyn.

56. [1685] The handsome, well-proportioned parish church of St. Mary Magdalen, Old Fish Street, Doctors' Commons, near St. Paul's.

57. [1685] The parish church of St. Matthew, Friday Street.  
 58. [1685] St. Clement, Eastcheap.  
 59. [1685] St. Mary Abchurch, near Cannon Street.  
 60. [1686] The handsome capacious parish church of St. Andrew, Holborn, one of the finest and most appropriate churches for the service of the reformed Church of England that has yet been built. The tower, which was not destroyed by the great fire, was repaired and faced with stone in 1704.  
 61. [1687] The parish church of St. Margaret Pattens, at the corner of Rood Lane and Tower Street. In ancient times this part of the city was the principal residence of the patten makers, hence its second name.  
 62. [1687] Repaired the banqueting house, Whitehall.  
 63. [1687] Finished the parish church of St. Michael, Crooked Lane. It was taken down by the authority of an Act of Parliament in 1830 to widen the approach to London Bridge.  
 64. [1689] Finished the College of Physicians, in Ivy Lane, Newgate Street. The gilt globe on its summit, intended, perhaps, to intimate the universality of the healing art, gave occasion to Garth in his "Dispensary," the scene of which is laid in this building, to say:—

"A golden globe, placed high with artful skill,  
 Seems, to the distant sight, a gilded pill."

65. [1690] Finished the Royal Military Hospital, Chelsea.  
 66. [1690] The parish church of St. Edmund the King, on the north side of Lombard Street, near the eastern end.  
 67. [1690] St. Margaret, Lothbury, opposite the north front of the Bank of England. It is one of Wren's best works.  
 68. [1690] Began the modern part of Hampton Court Palace, part of which was finished and occupied by King William and Queen Mary in 1694.  
 69. [1691] Surveyed and repaired the buildings used for the sittings of the House of Commons.  
 70. [1691] Built the Mint, or Moneyers' Hall in the Tower of London.  
 71. [1691] Finished the parish church of St. Andrew in the Wardrobe, near Doctors' Commons, where the Royal Wardrobe formerly stood, and so much spoken of in Pepys's Diary, when his kinsman and patron, Admiral Montague, first Earl of Sandwich, resided there as keeper of the Royal Wardrobe.  
 72. [1692] Finished the library, the quadrangle called Nevile's Court and other new buildings at Trinity College, Cambridge.  
 73. [1692] Made the new road from Hyde Park Corner to Kensington Palace, which was then becoming a favourite residence of King William III.  
 74 to 77. [1694] Morden College, Blackheath; Dartmouth Chapel, in the same village; Bohun's, or Boone's, Chapel, &c.  
 78. [1694] Finished the parish church of St. Allhallows, Lombard Street, a handsome spacious building, with an entrance only from the street, the church itself being in Ball Alley.  
 79. [1694] Also the spacious and well-proportioned parish church of St. Michael Royal, on the eastern side of College Hill, near Queen Street, Cheapside. In this church is Hilton's fine picture of Mary Magdalene washing Christ's feet, presented to the parish by the directors of the British Institution.  
 In this year the choir of St. Paul's was finished as far as the stone-work and vaulting, and the scaffolding, both inside and out, removed. Evelyn, who was a profound critic in architecture, as well as in the other branches of the fine arts, declared it to be a piece of architecture without reproach.  
 80. [1694] Converted the Benedictine Convent in the Savoy into a prison for state prisoners, who were then about to be tried, and as barracks for troops.  
 81. [1694] Built apartments for state prisoners of higher rank in the Tower of London.  
 82. [1695] Finished the plain substantial parish church of St. Mary Somerset, on the north side of Upper Thames Street, near Broken Wharf. It received its second name from the ancient church being built near to a small haven called Somers' Hut or Hithe.  
 83. [1695] Also the parish church of St. Vedast Foster, with its original and somewhat beautiful steeple, on the eastern side of Foster Lane, Cheapside.  
 84. [1695] Repaired the celebrated old English mansion of Audley End, in the county of Essex, about which a correspondence passed as to its dilapidated state between the Earl of Suffolk, who then occupied it as tenant under the Crown, having been purchased by King Charles I., and Wren, as surveyor-general.  
 85. [1696 *et seq.*] Began the completion of Charles II.'s unfinished palace at Greenwich, and built the additional wings, &c., to adapt it for a Royal Naval Hospital, by command of Queen Mary II.  
 86. [1696 *et seq.*] The parish church of St. Christopher, Threadneedle Street, taken down for Sir Robert Taylor's western wing of the Bank of England; its churchyard is now the garden in front of the directors' parlour, and visible on the western side of the first court from Threadneedle Street.

87. [1696 *et seq.*] St. Paul's Cathedral. The choir of St. Paul being finished, was opened for divine service on December 2, 1696, the day appointed for public thanksgiving for the victory and treaty of Ryswick.

1699. The beautiful chapel near the north-west corner of St. Paul's Cathedral, called the Morning Prayer Chapel, was opened for public worship, with appropriate ceremony.

88. [1699] The church of St. Allhallows, Barking, repaired.

89. [1699] Finished his exquisitely beautiful and geometrical tower and steeple of the ancient parish church of St. Dunstan-in-the-East, the body of which, not being much damaged by the great fire, was repaired by Wren, but the present body was built by Mr. Laing.

90. [1705] Finished the parish church of Isleworth, Middlesex.

In 1708 the outer cupola of St. Paul's was covered with lead.

91. [1708] Appointed one of the commissioners for building the fifty new churches ordered by Act of Parliament, and wrote his opinions as an architect thereon.

In 1710, when Wren had attained the seventy-eighth year of his age, the highest stone of the lantern on the cupola of St. Paul's was laid with masonic ceremony by Mr. Christopher Wren, the architect's son, attended by his venerable father, Mr. Strong, the master-mason of the cathedral, and the lodge of Freemasons, of which Sir Christopher was for so many years the acting and active master.

92. [From 1698 to 1723] The reparations and additions to Westminster Abbey.

93. [1711] The spacious and handsome church of St. Mary Aldermary, on the east side of Bow Lane, Cheapside, built at the expense of Mr. Henry Rogers, a pious and munificent citizen. The interior, although bold in design and ingenious in construction, is a defective imitation of the ancient Pointed style, with the additional defect of an altar-piece of the Roman composite order.

94. [1711] St. Thomas's Hospital, Southwark, began in 1692 and finished about this time.

95. [1711] Sion College, Aldermanbury, for the use of the collegiate body of "the President and fellows of the College of Sion, within the City of London," consisting of the parochial clergy of the city, with the Bishop of London as visitor. The ancient building was destroyed by the great fire, the present edifice began about two years afterwards, subsequently enlarged, and the new library added.

96. [1711] The building for the Royal Society on a site of ground presented by Mr. Howard, afterwards Duke of Norfolk, on his estate on the south side of the Strand.

PUBLIC HALLS. [1668 to about 1700] All the public halls of the Livery Companies of the Corporation of London, which, according to the second report of the Commissioners appointed to inquire into the Municipal Corporations in England and Wales, as regards the London Companies, printed by order of the House of Commons, April 25, 1837, amount now to eighty-nine, as the Commissioners excluded from their list several Companies which were practically extinct, or nearly so.

They consist of twelve chief Companies, whose arms are emblazoned, in their rotation, on shields over the capitals of the attached pillars in Guildhall, where the Livery meet in Common Hall. Of these halls Wren built the following between 1668 and about 1700.

97. [No. 1 of the twelve chief Companies] Mercers' Hall, on the north side of Cheapside, extending behind the houses from Ironmonger Lane to Frederick's Place, Old Jewry, in each of which streets it has an entrance. This fine and substantial building consists of the hall, court-room and offices, a handsome chapel, clerk's, architect's and beadle's offices, and residences for the clerk and beadle.

98. [No. 2] Grocers' Hall, in Grocers' Hall Court, on the north side of the Poultry. Wren's building was so capacious that a portion of it served for the use of the Bank of England when first established. It was taken down, and the present commodious building erected by Thomas Leverton. By the enlargement of the Bank, and the continuation of Prince's Street from Mansion House Street into Lothbury, the rear front of the hall now opens into that street, and gives the Company an entrance for carriages.

98. [No. 3] Drapers' Hall, on the north side of Throgmorton Street, a short distance westward of Austin Friars, Old Broad Street. It is a spacious and commodious building, replete with every accommodation for so wealthy a corporation. They are built on the site of the ancient palace of Thomas Cromwell, Earl of Essex, in Henry VIII.'s reign. It has been since repaired and a new street front, before Wren's quadrangle, by Robert Adam, the architect of the Adelphi Buildings, and other edifices of that mixed Greek and lower Roman style which stamps his works.

99. [No. 4] Fishmongers' Hall, well remembered by ancient citizens for its wine-cellars, wherein they drank their genuine old port and sherry, drawn from the casks, and viewed the bridge shooters and boat racers. It has given its name "Shades" to many others. Wren's buildings have given way

to the new bridge and the present plain, substantial and commodious building, by H. Roberts.

100. [No. 5] Goldsmiths' Hall, in Foster Lane, eastward of the General Post Office, St. Martin's-le-Grand. Wren's building was taken down about 1831, and the present larger, splendid, substantial, ornate building erected by Philip Hardwick, R.A. &c., soon afterwards.

101. [No. 6] Skinners' Hall, Dowgate Hill, Cannon Street. A spacious and commodious pile of building fit for this opulent Company and its officers. Like that of the Drapers, it has been substantially renovated, and a new street front added by Robert Adam, of Adelphi celebrity.

102. [No. 7] Merchant Taylors' Hall, on the south side of Threadneedle Street, nearly opposite the South Sea House. The hall or banqueting room of this building is reckoned to be one of the finest in Europe, and has been the scene of some of the most distinguished banquets ever held in the City of London.

103. Merchant Taylors' School, on the east side of Suffolk Lane, consisting of a large hall or schoolroom, with studies for the junior masters, a colonnade and courtyard for the pupils, a library, headmaster's study, and spacious residence for the same reverend officers.

104. [No. 8] Haberdashers' Hall, on the north side of Gresham Street West, at the corner of Staining Lane. This pile of buildings consists of the hall or banqueting-room, the fine foliated ceiling of which was destroyed a few years since, and a commonplace piece of vulgar lath and plaster put up in its stead. There are also houses and offices for the clerk, beadle, &c., next Gresham Street, and a chapel down Staining Lane.

105. [No. 9] Salters' Hall, on the western side of St. Swithin's Lane, Cannon Street. Wren's buildings were taken down, and a new hall and offices on a larger scale were erected by George Smith.

106. [No. 10] Ironmongers' Hall, on the north side of Fenchurch Street, nearly opposite Mark Lane. The street front is in a bold Italian style of a more recent date.

107. [No. 11] Vintners' Hall, on the south of Upper Thames Street and the approach to Southwark Bridge. The front court and gardens at the back of the hall, which looked on to the Thames, was a minor Campus Martius at the beginning of the French revolutionary war for the Vintry Ward volunteers to drill and practise their military exercises.

108 [No. 12] Clothworkers' Hall, on the eastern side of Mincing Lane, Fenchurch Street. It was not entirely consumed in the great fire, and some ancient wainscoting, with figures of James I. and Charles I., and a window of stained-glass, decorate the dining-hall.

Other halls of the minor companies, many of which are of great wealth, although the first twelve have had precedence and certain privileges and estates in the province of Ulster, in the kingdom of Ireland, given them by James I. for aiding him with funds for establishing a Protestant plantation or colony in that portion of the sister island.

109. [No. 13] Dyers' Hall, on the north side of Great College Street, Dowgate Hill, rebuilt on a larger scale.

110. [No. 14] Brewers' Hall, on the north side of Addle Street, Aldermanbury, a spacious, commodious hall and offices.

111. [No. 15] Leathersellers' Hall, at the bottom of St. Helen's Place, taken down and rebuilt on a larger scale by W. F. Pocock.

112 [No. 18] Cutlers' Hall, on the south side of Cloak Lane, Dowgate Hill.

113. [No. 19] Bakers' Hall, on the eastern side of Harp Lane, Great Tower Street.

114. [No. 21] Tallow Chandlers' Hall, on the west side of Dowgate Hill, a handsome and spacious building with an interior colonnade of the Tuscan order, and for London the singular addition of a circular basin and a fountain throwing up a jet of water from a conch shell blown by a cupid.

115. [No. 23] Girdlers' Hall, on the eastern side of Basinghall Street. Although the business of a girdle-maker is no longer extant among City trades, yet the ancient and worshipful Master and Wardens of the art and mystery of the girdlers of London are trustees for several very excellent charities.

116. [No. 25] Saddlers' Hall, on the north side of Cheapside, between Gutter Lane and Foster Lane.

117. [No. 27] Cordwainers' Hall, on the north side of Distaff Lane, Doctors' Commons. The hall has been remodelled and thoroughly repaired, and a handsome stone-fronted building for offices, &c., added to it by Robert Adam.

118. [No. 28] Painter-Stainers' Hall, on the western side of Little Trinity Lane, Upper Thames Street. The livery-hall or refectory is a handsome, well-proportioned apartment, with a plaster-modelled ceiling, painted with allegorical subjects by Fuller. This hall is worthy of notice for the fine collection of pictures by Palmatier, Brull, Hungis, Houseman, Reynolds, &c., many of whom were members of the Company.

119. [No. 29] Curriers' Hall, on the south side of London Wall, near Wood Street.

120. [No. 30] Masons' Hall, in Masons' Alley, between

Basinghall Street and Coleman Street; a small but commodious structure formerly used by the Grand Lodge of Freemasons; since that time for various other purposes, as for auctions, debating societies, and more recently for a tavern and public dining-rooms.

121. [No. 31] Plumbers' Hall, on the eastern side of Great Bush Lane, Cannon Street. It was pulled down and its site covered by lofty warehouses.

122. [No. 32] Innholders' Hall, at the corners of Great and Little College Streets, Dowgate Hill.

123. [No. 33] Founders' Hall, in Founders' Hall Court, Lothbury, taken down for the improvements between that street and Moorfields.

124. [No. 36] Coopers' Hall, on the western side of Basinghall Street, near to the eastern entrance of Guildhall. It is a large, substantial building, the banqueting-room of which, wainscotted to the height of 14 feet, and paved with marble, was formerly used for drawing the state lotteries. It has commodious offices, and residences for the clerk, beadle and other officers of the Company.

125. [No. 37] Tilers and Bricklayers' Hall, on the south side of Leadenhall Street. It was formerly let as the synagogue of the Dutch Jews in London, but is now occupied by a literary and scientific institution and called Sussex Hall, after His Royal Highness the late Duke of Sussex.

126. [No. 41] Joiners' Hall, on the east side of Joiners' Hall Buildings, Upper Thames Street, near Dowgate Dock, but has been let to a packer and used as extensive warehouses.

127. [No. 42] Weavers' Hall, on the eastern side of Basinghall Street.

128. [No. 46] Plasterers' Hall, Addle Street, Aldermanbury. A substantial and spacious hall, court-room and offices.

129. [No. 47] Stationers' Hall, on the western side of Stationers' Hall Court, Ludgate Hill. A spacious and well-proportioned hall, with court-rooms, clerk's and beadle's dwelling-houses, warehouses for their stock, &c. The hall and offices underwent a thorough repair, the eastern front cased with stone, and the roofs new guttered and slated by Robert Milne in 1805. There are some excellent pictures of the English school in the court-room, presented by Alderman Boydel, who was a past master of the Company.

130. [No. 38] Apothecaries' Hall, on the eastern side of Water Lane, Bridge Street, Blackfriars, one of the largest halls in the City, with elegant court-room, spacious dining-hall for the members of the Society, pictures and busts of benefactors. The warehouses, drug mills, laboratories, &c., are of more recent date.

131. [No. 68] Pinmakers or Pinners' Hall, on the north side of Old Broad Street, near Winchester Street. The livery hall was for some years used as a Dissenting meeting-house, and subsequently the whole building as commercial chambers and offices.

132. [No. 79] Coachmakers' Hall, Noble Street, Foster Lane, Cheapside, is a spacious and was a handsome hall, with court-room, offices, &c., built originally for the worshipful Company of Scriveners, which, falling into poverty, sold it to the wealthier Company of Coach and Coach Harness Makers. They, in their turn, went downwards in the wheel of fortune, let it for balls, concerts, a dancing school, and during the first years of the French revolution to the less harmonious purpose of a political debating society, in which many demagogues and some orators of after distinction made their earliest rhetorical essays.

To these authenticated and enumerated works may be added many of the almshouses of these companies, humble, but like those of the Merchant Taylors' Company, at Lee, founded by Mr. Bohun, or Boone, bearing the hall-mark of a master in his art; many fine mansions in the City, as the Deanery House of St. Paul's, and its entrance from St. Paul's Churchyard; one on Laurence Pountney Hill, Cannon Street; two on College Hill, with their sculptured pediments; one in the Old Jewry, formerly used by the London Institution till it was removed to their new building in Finsbury Circus; and many others, which have been pulled down; two in Chichester, besides repairing the cathedral, which would fairly raise the number of Wren's public works to an average of at least 150—an unprecedented number for one man.

Nearly all these great works can be surveyed from one spot, the stone gallery of the cupola of St. Paul's, whence they may be viewed as in a panorama. "Circumspice."

## THE ANTIQUITIES OF CULLEN.

IN an article in the *Glasgow Herald*, Mr. J. M. Mackinlay writes:—

Cullen has a unique position among Royal burghs, as it is the only one that has changed its site. It once stood close to Cullen House. Newte, who was there in 1785, described the place as "a small, poor town, without one good house in it." About thirty-seven years later the town was demolished to

allow the grounds of Cullen House to be extended, and was rebuilt a short distance further to the north-east, nearer the sea. With the exception of the parish church in the midst of its burying-ground, and a portion of the factor's house, nothing now remains of the old town. The new town has a population of about 2,000. It is regular in plan and has a spacious square, where stands the burgh cross, the shaft dating from the time of William and Mary. The cross bears the town's arms, the Virgin and Child, the same as those of the Border burgh of Selkirk. It stood in the old town till about 1822, when it was removed to the Castlehill. There it remained overlooking the sea till 1872, and was then transferred to its present site. A plan of the old town of Cullen, dating from 1762, serves to show its appearance. Much light has been thrown on its bygone ways by Dr. Cramond, whose painstaking researches have made all antiquaries his debtors. Cullen House, already referred to, is the Banffshire seat of the Dowager Countess of Seafield, by whose courtesy visitors are admitted to the beautiful grounds. The mansion is a picturesque structure, built about 1602, but considerably altered since then. It stands on the brink of the narrow ravine where flows Cullen Burn 50 or 60 feet below. The house contains many curious and valuable specimens of tapestry, woodwork and china, as well as paintings. The library is most attractive both as regards its contents and the apartments where the books are housed. Outside a couple of large stone lions guard the entrance, while on the walls are carved representations of the three theological virtues, Faith, Hope and Charity, with the mottoes:—

- (1) FAYTH YE GRVND OF AL.
- (2) HOPE YR ANKER OF FAITH.
- (3) CHARITIE COVERETH MANIE SINS.

These are believed to date from about 1668. Cullen House suffered during the second Stuart rising, having been plundered by some of Prince Charlie's followers on April 8, 1746. Close to the house is a substantial one-arched bridge spanning the burn, and a little higher up the stream is another bridge, also of one arch, but considerably older and more picturesque, called the Lady's Bridge. The grounds abound in splendid trees of different kinds, and a good road leads by a tolerably gradual ascent to the top of the Bin of Cullen, whence a magnificent view over sea and land can be had on a clear day. A building much older than Cullen House once stood not far from it, and served as the occasional residence of royalty. A fragment of the building was to be seen at the end of last century, but nothing of it is now visible. It is believed to have been occupied by Alexander II. and Alexander III., who visited Cullen probably to enjoy the pleasures of the chase in the then extensive forests of Boyne and Enzie. Elizabeth de Burgh, daughter of the Earl of Ulster and second wife of King Robert the Bruce, is believed to have died within its walls. Part of her body was buried within the church of Cullen, and the remainder was interred in Dunfermline Abbey. Her husband bequeathed a sum of money for the support of a chaplain in the church of Cullen to pray for the repose of her soul.

No one can fail to be attracted by that noteworthy relic of old Cullen, its parish church, dedicated to St. Mary. In the year 1236 we hear of the chapel of "Inverculan" in connection with a dispute as to jurisdiction between the Bishops of Aberdeen and Moray. The term "ecclesia parochialis de Cullan" was used in the sixteenth century as pointing probably to the possession of baptismal rights, but Cullen did not attain to the dignity of a separate parish till early in the seventeenth century. An important change was made in the condition of the church in 1543. Not only was the structure rebuilt on a larger scale, and joined to St. Anne's Chapel erected a few years before, but the whole was made a collegiate church for a provost, six prebendaries and two singing boys. The prebends created were those of St. Anne, Holy Cross, St. Mary, St. John the Baptist, St. Andrew and St. Mary Magdalene. The holder of St. Anne's prebend was to be the precentor of the college, and had to teach daily a song-school for boys within the church. The prebendaries had their duties clearly stated in the foundation charter. They were required, *inter alia*, to reside near the college, and to officiate daily within its walls. On feast days they were to be dressed in clean linen surplices with hoods of red fur, and, thus attired, to say matins, high mass, vespers and compline at the great altar in the choir, and after compline to repeat nightly the *Salve Regina* in the chapel of St. Anne. There were burials within the church both before and after the Reformation. The last interment was that of the Dowager Countess of Findlater, who died in 1795. The church contains some fine monuments. The best is that of its founder, Sir Alexander Ogilvy (founder also, it is believed, of the ancient bedehouse of Cullen, and ancestor of the Earls of Findlater and Seafield). It is in the form of an arched recess, containing elaborate carvings. In the recess is seen a stone figure of the knight, with his hands folded on his breast as if in prayer. The late Andrew Jervise, of Brechin, an authority in such matters, speaks of this sepulchral monument as possibly one

of the finest in the North of Scotland. There are some marble monuments in the church. One of these is to James, fourth Earl of Findlater, the chancellor earl, as he has been called, who did much to bring about the Union of the two kingdoms in 1707. It is related of him that when the Scottish Parliament rose for the last time he exclaimed, "There's the end o' an auld sang." When rebuking his brother, the Hon. Patrick Ogilvy, of Inchmartin, who was no friend of the Union, for being a cattle dealer, he was met with the retort, "Better sell nowt than sell nations." Till 1877 his monument stood beside the north wall of the church and completely concealed an interesting relic of pre-Reformation times in the form of an aumbry or sacrament-house for holding the consecrated elements. This sacrament-house is constructed of freestone and is 8 feet high and 3 feet broad. The small recess, or aumbry proper, had formerly a door and lock. Above it are carved representations of two angels with uplifted wings, holding in their hands a monstrance or vessel wherein was placed the consecrated wafer. Above the angels is an appropriate inscription in Latin. About the year 1800 the present north aisle of the church was built. Some forty-two years later the old seats in the south aisle were removed, and their carved wood was preserved by being fixed to the pillars of the Seafield gallery. The churchyard is surrounded by high walls, and contains some fine trees and a number of venerable lichen-clad tombstones. About half a mile from the graveyard to the west is St. Mary's Well. Water from the spring is said to have been used in the services of the church. Till comparatively recent times, Mary Fair was held in the town on the third day of September, a survival of the festival commemorating the nativity of the Virgin.

## THE PHYSIOLOGY OF TASTE.

PLEASURE and pain are ultimate facts in the animal economy. To perceive and to judge them is the same act, and simply to name them is to define their character. To the percipient their quality is matter of absolute certainty, and their nature cannot be made clearer by reasoning. But this distinctness of our sensations is confined to the being in whom they exist. No language can explain to the inexperienced bystander what is passing within or convey to him the remotest idea of the impression in question. He must have felt the affection himself before he can understand it. The sensorium of each individual is therefore at once its own world and its own law, and all judgments of external nature in its relations to sensation can have no other standard. This truth is embodied in the familiar adage, "*De gustibus non est disputandum*."

But this very intensity of our own sensations, the certainty we feel of what passes within us, creates a disposition at every instant to dispute the tastes of others, and to assert the supremacy of our own judgments in matters of feeling. The constant operation of this tendency has led to inquiries into the nature and causes of our sensations, and to an attempt to discover some general and abstract type of beauty and of good by which the particular sensations of individuals may be safely compared.

Experience, however, exhibits a marked and rather extensive range of differences in the results of sensitive impression, when made by the same object on several individuals. If a picture, for example, be presented to the consideration of a mixed company, the judgments passed upon it will be widely different: "*quot homines, tot sententiæ*." In some, perhaps, it will excite no sensation of pleasure or pain whatever, and scarcely any idea beyond that of a variously-coloured canvas. The greater number will, in all likelihood, praise or censure it in the gross, thereby proving that their sensations concerning it are vague and indistinct. A few, more discriminating, will each seize upon some specialty for remark—its colouring, grouping, drawing, design or execution; and, judging the picture exclusively on that ground, prove that their pleasure is of a different origin from that of their neighbour.

On the other hand, there are, confessedly, certain points on which most sane men agree; there are particular forms, colours and sounds in nature and art which generally please, and the manner in which their combinations affect mankind at large is visibly subordinated to general laws. The more any art is cultivated, the greater is the tendency in its professors to lay down certain rules for governing their designs, and to believe that there exists in nature something absolute and definable by which individual taste may be estimated and corrected. It is, however, chiefly by the contemplation of generalities that the mind is led to this conclusion, for the more it descends to particulars the greater is the evidence of innate and acquired differences of feeling between man and man and the greater the difficulty of getting society to agree on specific truths.

Pressed upon by two orders of facts thus contradictory, philosophy has hitherto been unable to arrive at any universally admitted opinions concerning abstract beauty or the possibility

of arriving at certainty in matters of taste. This obscurity, overhanging a subject after the lapse of so many ages of dispute, is clearly referable to the mode in which it has been treated and to the bad metaphysics in which it has been involved. The doctrines of taste lie not in that imaginary world yclept "the eternal nature of things," nor do they depend merely upon the physical properties of external nature. Taste is altogether an affair of sensation, and its laws are, and can be, no other than those of the living machines of which sensation is the attribute. The theory of taste is part of the natural history of man; and, if its doctrines are of uncertain application, it is only in as far as that history is incomplete, or is ill-understood by the æsthetic philosopher.

If there be any physiological truth more clearly ascertained than another it is this: that nature is made up of individuals, that species and genus are the figments of the human brain, and that their common identity is obtained by the ideal abstraction of an infinity of particulars. The sensitive susceptibilities of individual men, like their minute organisation, are strictly personal; and they differ as to a multitude of nameless phenomena, not only in different persons, but in the same individual at different epochs of his existence. This may be affirmed generally of all our pleasures and pains; but it is more exquisitely true with respect to the more refined and delicate sensations, to which the term taste is more especially confined.

In respect to these sensations, mankind may be roughly divided into three classes—the intellectual, the sensitive and the sensual. The first class embraces those in whom the reflective faculties predominate over the organs of sense; their vitality is internal, and is habitually concentrated on the operations of their own minds, almost to the exclusion of the phenomena of the external world, where these are not immediately concerned in the preservation of life. In the second class, on the contrary, the intellect is all abroad; all the external impressions are vivid, and, the parties being occupied but little with reflection, they exist almost entirely in their sensations. The third class contains those whose moral existence is of the lowest order—whose nature is most purely animal—and whose being is principally wrapped up in the gratification of their appetites. The types of these classes are sometimes found in considerable accuracy and perfection: more usually it is a simple predominance of one set of faculties over the others that constitutes the sub-genus. The predominance exists under an infinity of shades and gradations, and each shade is accompanied by its own especial range of sensibility and affection from external objects. The devotees of the fine arts belong principally to the second class, for the qualities of objects must be distinctly perceived before they can become the causes of pleasure or of pain. The intensity of that pleasure or pain, however, seems to depend on some other peculiarity of the constitution. The power of perceiving, though essential to a susceptibility to emotion, does not always awaken it. There are men in whom deformity, when rendered an object of distinct cognisance, excites no disgust, and who behold the most admirable works of art and nature with a stupid indifference.

Besides these broader distinctions between man and man, which may be designated as temperaments of the sentient complex, there are personal idiosyncrasies as to minuter particulars too numerous for arrangement. Some persons exhibit in their observation of the arts a peculiar sensibility to form, others to colour; others, again, uninfluenced by form or colour, are especially alive to the pleasures of sound. There are men exclusively affected by sequent sounds, on whom the combinations of harmony produce no definite effect; and there are exquisite harmonists who are little touched by the effects of melody. There are also those who (probably through defect of the organ of sense) dislike music of all sorts. Descending to more minute particulars, there are persons exclusively attached to vocal music, others requiring the stimulus of powerful bands, some touched by martial, others by plaintive melodies. Savage nations appear generally to affect the minor keys.

The amateurs of painting may, in like manner, be divided into three distinct classes—those most touched by the ideal, those chiefly curious as to the mechanical departments of art, and, lastly, the lovers of nature, who are the most powerfully affected by the beautiful in landscape. The determination to any one of these preferences, whether it be considered as innate or acquired, is a fact which detracts from the universality of the principles of taste. The preference is a phenomenon natural to the being in which it is manifested; and, as it is a natural, so it is a true taste. Between the several schools of painting, therefore, there can be no common beau ideal to which to appeal; on the contrary, each has its own laws, its own canons of criticism; and the same picture may be perfection to one man, without exciting an emotion of pleasure in another. Who then shall decide between them?

Another great physiological truth that bears against the certainty of taste is, that the specific pleasures and pains attached to externals in any one organisation are liable to be

loosened from the causes by which they were originally excited. It is a law of the animal economy that use shall blunt the force of sensitive impression, while it develops the intellectual clearness of the idea excited by an external. Thus, experience in the arts, by diminishing enthusiasm, abates the sum of pleasure derivable from that source, and a greater degree of merit becomes requisite to produce an equal sum of agreeable effect; at the same time, the increasing accuracy of perception opens a new range of ideas for comparison, and that which formerly excited pleasure as a merit may be afterwards a source of pain as a defect. Every new sensation that we receive may be rendered a means of modifying the range of pleasures and pains; and there is, consequently, an education both of the organs of sense and of the intellect that unsettles taste, and subjects it to a perpetually progressive refinement. Under the influence of habitual exercise, the eye sees more and more of its object, and the mind judges with greater finesse. The observer thus arrives at a more exquisite perception of beauty, and rejects with disgust the objects of his previous admiration. It is by these means that a single artist, dissatisfied with the works of his predecessors and with his own progress, may be driven to look beyond what actually exists in art, and to go in search of hidden sources of beauty, by which, when attained, he creates new standards of excellence, to influence the general sentiments of an entire nation. Each age thus acquires a taste of its own; and the hard lines and unreal flatness of Giotto, which were, to Dante, the perfection of painting, were thus rendered intolerable when Raphael and Domenichino had taught Italy a better style. Dante's criticism on Cimabue,

Credette Cimabue nella pintura  
Tener lo campo, ed ora ha Giotto il grido,

contains the whole history of the arts. "Le mieux est l'ennemi du bon;" and, for aught we can tell, a future race of artists may lay open a new series of beauties that will discredit all that has hitherto been effected in painting and sculpture. In judging, therefore, of any specific work of art, the learned critic makes reference to the age in which it was produced; and, by a curious particularity in the phenomena of sensation, not only does the intellect decide in favour of any work which exceeds the average merit of its own time, but the sensorium derives pleasure from it when so judged; whereas, if viewed without reference to such a principle, pain might be the only result.

Connected with this law of the economy is an uncertainty in taste of an opposite tendency. The liability to satiety, leading to the pursuit of novelty, produces from time to time a conventional and vitiated love of certain mere extravagances by which the arts are degraded.

Such caprices, indeed, are seldom permanent, nor are they even for the time largely participated by those who feel or who think for themselves. Still, while the fashion lasts the pleasure excited is real, and it detracts *pro tanto* from the universality of principles. Occasionally, however, traces of such ephemeral judgments may remain to after times and modify to a certain extent the sensibility of future generations.

In enthusiastic temperaments it is the sensation of pleasure or pain which a work of art excites that fixes the attention upon it and provokes criticism. Such persons judge because they feel. There are others in whom this process is reversed. The love of the arts as marking a finer organisation is regarded as a distinction, and many are drawn to their study by vanity, ambition and the instinct of imitation. This class, if they really feel, feel because they judge. Their pleasures pass through their understanding, and are founded on the perception of fitness rather than on mere physical sensation. The certainty of their judgments does not extend beyond the sphere of their experience, and is confined usually to some particular school or master beyond which their notions are vague, vacillating and undirected by general principle or by sentiment. These stop-watch critics, as Sterne has called the brotherhood, form a school of taste apart, and their judgments follow a different law from that which directs the opinions of the man of feeling. Their "Correggio and stuff" disgusts the genuine enthusiast, but still it is their taste.

A large part of the pleasures of taste arises from association of ideas, a circumstance powerfully tending to vary men's affections by works of art. The simplest sensations we receive involve a judgment; we judge that we are changed in our own being by the sensation; and we judge something concerning its external cause. In our ordinary existence there are very few sensations that do not excite several such judgments; and such judgments, when of frequent occurrence, become so closely associated with the sensation as to be mistaken for a part of itself. Thus, to take a familiar instance, the unlearned think they see distance. There are certain particular forms which, by a very obvious causation, provoke judgments concerning the utility of the object, and this judgment powerfully influences our sense of its beauty. A high-blooded racer and a strong bony cart-horse are diametrically opposed to each other in the

details of their form. There is in each of these animals, however, a certain symmetry of parts which fits it especially for a specific purpose, and the specimen that possesses these distinctives in an exquisite degree is in both cases deemed beautiful. It is true that, as far as natural objects are concerned, there may be a necessary harmony in the parts whose organisation all tends to one given end, so that the perfection of function and beauty may go together; but we apply the epithet of beautiful to artificial machinery and speak even of a beautiful experiment in chemistry. In these cases the pleasure derived from a sense of the utility connected with a form seems to the percipient to flow from the form itself and to be really a physical quality. By a similar mental process moral antipathies engender the idea of ugliness, while physical deformity sometimes excites moral aversion. Hogarth's waving line of beauty is to many persons odious in a serpent and in all serpentine movements; and it is likely that the popular reputation of the toad for possessing poisonous qualities is derived from the unpleasant aspect of the animal. The influence of this association is strong in our perceptions of physiognomy. A sinister expression of countenance destroys the effect of beauty of feature, while an expression of benevolence redeems a face decidedly plain. If by time or accident such associations become dis severed, the judgments also respecting beauty are changed. A spider is considered beautiful by those whose nursery notions are superseded by juster impressions of the industry, sagacity and harmlessness (to ourselves) of the animal. The story of "Beauty and the Beast" is an illustration of this law.

It is a matter of surprise to many that objects in themselves ugly may become agreeable in imitation. A trim architectural drawing of a commodious house is less pleasing than the picture of a dilapidated cabin; a soldier in regimentals makes a less effective picture than a beggar in rags, and a park is not so picturesque as a wild forest. This seems to result from an association of ideas. The idea of utility is in this case totally dis severed from the sensation and is superseded by another. The pleasure excited by picturesque objects consists in a certain exaltation and poetic enthusiasm, and experience abundantly shows that the organisation is the most susceptible of this condition when the frame is braced by exercise and by the pure air of the country. It is then that visible objects produce their strongest effect, and that the senses go as it were abroad, in search of the sources of this species of pleasure. The escape, too, from the trammels of society and from the low cares of business favours this predisposition. It would seem, then, that those objects which habitually present themselves to contemplation in such moments of exaltation have a tendency to reproduce the state when seen in imitation, while the familiar objects of our artificial life in cities tend, when painted, to chill and to narrow the feelings. In the works of man, also, straight lines (the shortest in statistics as in geometry) predominate; their beauty, therefore, is naturally small, consisting principally in utility, and it disappears when that utility becomes too obviously a secondary consideration. In these works also all is violence and restraint; they are indications of difficulties surmounted, of labour exerted, and of a mind painfully fixed on a few disgracious ideas. In nature, on the contrary, the productions seem more spontaneous; its pleasures appear a free gift of Providence to man, inviting the mind to repose, to reverie, and to tranquil enjoyment. Almost every natural object, therefore, pleases in painting, from its power of producing an associated reminiscence of the excitement which that or similar objects have occasioned in the original. One almost fancies the cool breath of the wind passes over one's face in viewing a well-painted piece of forest scenery, and all the pleasing reverie of "the melancholy Jacques" seizes on the mind as the contemplation lingers over it.

What the picturesque is in art the noble is in poetry. A recurrence to the miserable necessities of humanity destroys alike the sublime of both, and it is the moral association that makes the beauty of either. Whatever tends to disturb this association of ideas destroys the picturesque; a group of modern hunting squires in red coats would assuredly spoil the effect of forest scenery as far as this beauty is concerned, whereas a boar hunt conducted by persons habited in the costume of a remote and poetic age would enhance it. Further, it may be remarked, that any other association capable of producing the same tone of mind creates picturesque beauty. A fine piece of Greek architecture recently constructed, however beautiful, will not be deemed picturesque, but the same forms and proportions partially overthrown and ruined become picturesque by the grandeur of the historic ideas they are calculated to recall. Certain forms not improbably receive this quality through an exaltation of mind, produced by a mere sense of the art bestowed on their representation. All broken forms creating minute diversities of lights and shades, the fluttering rags of the beggar, the lichen on the stone, the diversity of rock, &c., require a far higher exercise of imitative power to reproduce than smoother, and in themselves more elegant, forms. The

pleasure which the knowledge of this fact creates and the feeling it excites constitute the charm of the accurate imitations of the Dutch school.

Inappropriateness, by interfering with association, destroys picturesque effects. The ass, which paints so well in a woodland scene, has no such charm if placed in a garden; nor would the peasant's cottage be picturesque as part of a street of palaces.

To the sense of picturesque beauty, education and a cultivated enlargement of mind powerfully contribute. In proportion to the variety of the beholder's knowledge is the sphere of his possible associations. A work of art, acting upon the *elegans formarum spectator*, the accomplished amateur and scholar, excites long trains of reflection, embracing numerous analogies in the physical and ideal world, comparisons with former experience, poetic illustrations, historical remembrances, speculations on cause and effect, &c., by which an enthusiastic elevation or ecstasy of the mind is begotten—an exaltation of which the ruder intellect is not susceptible. This pleasure, though reflective, is ultimately referred to the senses, with whose impressions it is so intimately connected, and to the external objects by which they are excited. In this vast and extended field circumstances are all-powerful to determine specific tastes. The Dutch, who, by nature and social position, were cut off from the access of such enthusiasm, had little feeling for ideal beauty. They saw in the arts nothing that was not imitative, and they had no taste for anything in representation but the naked matter of fact. Whatever transcends the ordinary aspect of ordinary nature was lost upon them, and their minds, preoccupied with the positive ideas of commerce, were excited by the metallic lustre of a brass pot, or an effect of light on a glass bottle, well represented, more than by all the splendour of a landscape by Claude, or the beauty of a Madonna of Murillo.

Inasmuch, then, as every man is born with his own peculiar temperament, and is exposed by the accidents of life to his own specific moral and intellectual education, he is liable to be affected in his own peculiar manner by external objects. The same is true, also, respecting nations; inasmuch that each separate community has its own specific taste in literature and the arts, and cannot be brought to acknowledge beauties which do not harmonise with it. But amidst the infinite varieties of idiosyncrasy, temperament and education, there is a general tendency in the human organisation towards a middle term or common character which lies equally distant from all extremes. To this middle term no man perhaps has ever absolutely attained, yet all approach it in some particulars. To it, as Quetelet has well observed, all general reasonings on man, whether physiological, moral, political, statistic or æsthetic, should be referred. It is the universal scope of all abstract reasoning on our nature. It is by the contemplation of the largest number of individuals that the most accurate notion of this middle man is derived, and by abstracting from each all that is personal and exceptional we arrive at what is embraced by the term human nature.

By the study of this middle man the philosophical artist is enabled to arrive at certain general truths or principles of taste which are susceptible of a more or less happy application in his attempts to captivate the applause of society by his labours. To this middle nature alone is any abstract doctrine at all applicable. But the tendency of society and civilisation is to bring all men nearer to such a type, and the cultivation of the intellectual powers consequently produces a closer agreement of opinion as to the sources of pleasurable sensation. What thus takes place among individuals occurs equally among nations. The steps by which society in one country advances in civilisation may differ in many particulars from those of others. The "middle man," or ideal type of humanity, therefore differs in each. The Frenchman differs in his tastes, as in his prejudices, from him of Germany or of England as to almost everything not derived from the common fountains of classical antiquity or of the Christian religion. The Italian, Flemish, French, and English schools of painting stand upon distinct canons of criticism derived from distinct habits respecting pain and pleasure, and they are perfect incommensurably. But from the moment when the printing press and improvements in communication brought the nations of Europe into a closer contact these national peculiarities began to give way, and a continual approach has been making towards a middle nature which will eventually constitute the common type of civilised man. The French under this progress have abandoned their ancient tastes in tragedy. Shakespeare is esteemed in Paris, and Goethe has his admirers in London.

But if the doctrines of taste are calculated upon this middle nature it is obvious that, as in every individual, there is a more or less near approach to that condition, and as there is a large mass of particulars which are common to all, the susceptibilities to pleasure and pain (however they may differ in different persons) must be governed by one common law in every man. There are, accordingly, some principles of taste arising out of these universals which are equally universal, and upon which

every sane man is agreed. The certainty of these principles is absolute. Next in order to these are the points on which all large communities are agreed. The maxims of taste governing any great national school of art are certain with respect to all the individuals rigorously bred in that school, and the individual who presumes to impugn them on the spot will infallibly lose his character there for taste and judgment. After such national peculiarities follow the peculiarities of taste arising from differences of temperament and idiosyncrasy. These respectively are sufficiently common to be acknowledged as part and parcel of humanity; and a man is not sent to Coventry or to Bedlam for confessing that he indulges them. There are other less common deviations of feeling and judgment which are laughed at as eccentricities and oddities, or haply repudiated as affectations, while the lowest degree of toleration only is given to the still less frequent peculiarities which are attributed to vicious or defective organisation.

Good taste therefore stands upon the same foundation as orthodoxy in religion: it exists only by the suffrage of the majority. To each man his own affections are the standards of taste, as his opinions are the standards of orthodoxy, and it is only when he meets with a formidable opposition from a numerous body differently constituted from himself that he can be persuaded to tolerate any deviations from these standards; an isolated individual necessarily knows no others. Experience alone can teach us that other men are differently affected and that their affections are entitled to an equal respect with our own. Thus it is that knowledge of the world cures men of arrogance and intolerance, and enlarges their sympathies. The steps of this progress are distinct. We first sympathise only in the affections which we have ourselves experienced; afterwards we learn to tolerate those the most analogous to our own; and finally, we are patient of feelings which, not sharing ourselves, we yet perceive to be common to many sane and worthy fellow creatures.

In proportion as our idea of human nature is extended by the aspect of man under a greater variety of circumstances, the field of taste is enlarged, and the tolerance of other forms than those which the individual has been accustomed to regard as pleasing insensibly leads to a change in his own sensations.

In proportion, then, as a judgment or sentiment is divergent from the feelings common to society, it is censured as bad in morals, erroneous in opinion or false in taste. We do not insist on our friends liking the same meats as ourselves, because diversity on this point is of every day's experience; so society tolerates the forms of religion with which it is familiar, while it refuses liberty of conscience in favour of opinions which are new and strange. Whatever, on the contrary, is common to the majority, passes for truth, rectitude and good taste. The preference of one art or one school over another is sufficiently common to exempt it from the imputation of bad taste, but if we should meet with an individual delighted with the music of a penny trumpet, in ecstasies over a drawing on a Chinese saucer, or preferring a Nuremberg doll to a statue by Thorncroft, it would be a great stretch of charity not to set him down as utterly mad.

A feeling for the fine arts being, however, the result of a peculiar organisation, common only to a few individuals, and the sensitive faculties being capable of great development by exercise, it has come to pass that the civilised world has taken its judgments very much at second-hand. *Cuilibet in arte sua credendum* is here a maxim of especial applicability. The rules of taste are generally adopted from the professors of art, and, in proportion as the arts are cultivated, a greater certainty is given to such rules, and the more safely may bad taste be inferred from their violation. But rules, after all, are only the means to an end; the great fundamental consideration is the effect produced. If that be consonant to the feelings of the sensitive and the educated, the main end of art is obtained. In all, therefore, that is not merely mechanical, rules are conventional chains, and genius is right in neglecting them. Still, to violate a rule without obtaining a redeeming excellence is bad taste—to obtain new beauties, no matter how, is good taste. In modern music discords are used which would have startled and shocked the ancient theorists; in these cases success alone justifies, and public opinion, consequently, is the sole criterion of right and wrong.

If due consideration be given to what is universal in the nature of man, and what is divergent and particular to individuals, there can be little difficulty in determining the bounds of taste as a science, and of deciding what is and what is not within its domain.

There are objects which confessedly affect all mankind alike—the murmuring of waters, the singing of birds, the freshness of the morning, the still repose of evening, the majestic spectacle of the starry heavens, the refreshing verdure of the earth, produce their common influence upon the well-organised of all natures and ages. With respect to these, and to other such generalities of our nature, general reasonings may be indulged, and a corps of doctrine laid down which, as a theory, may be made to throw valuable light on the subject of art.

But even within this limit the application to specific instances is difficult and fallacious.

The comparison of such archetypal ideas with individual works of art is a pure operation of judgment, and the judgment of the individual is the result of his personal tastes, of the degree of culture his senses have received, of his associations and his prejudices; while rules thus obtained are worth nearly nothing when applied to what is absolutely new in art. The most experienced critics often err, and but seldom agree with each other, if not as to the specific merits of a master or a work, at least as to the relative degree in which these merits are predicable. With respect to the mass of mankind, the little unity of opinion subsisting among them may, after all, arise as much out of deference for established authorities as from a want of common feeling.

It is, however, on the ideal points that this difficulty is chiefly felt. With respect to the mechanical departments, decision is more easy. Errors of drawing or of perspective are matters of demonstration; a false insertion of a muscle can be compared with the human subject; a displaced line can be detected by a diagram; even defects of drawing and aerial perspective may be shown by comparison. It is on these little matters that little critics are great; but when the more transcendent order of ideas and sensations comes in question, there is no criterion but feeling, which in each individual is a definite fact *sui generis*, from which there is no appeal but to the feelings of another observer, and whatever is so circumstanced remains an object of endless and unsatisfactory debate.

## TESSERÆ.

### The Public and Art.

THE artist and the public are ever in the strictest reciprocity; if the arts flourished nowhere as in Greece, no other nation ever interested itself with motives so pure in their establishment and progress, or allowed them so ample a compass. As long as their march was marked with such dignity, whilst their union excited admiration, commanded attachment and led the public, they grew, they rose; but when individually to please, the artist attempted to monopolise the interest due to art, to abstract by novelty and to flatter the multitude, ruin followed. To prosper, art not only must feel itself free, it ought to reign; if it be domineered over, if it follow the dictate of fashion or a patron's whims, then is its dissolution at hand. To attain the height of the ancient was impossible for modern art, circumscribed by narrower limits, forced to form itself rapidly, and on borrowed principles; still it owes its origin and support to nearly similar causes. During the fourteenth, and still more in the course of the fifteenth century, so much activity, so general a predilection for art spread themselves over the greater part of Italy, that we are astonished at the farrago of various imagery produced at those periods. The artist and the art were indeed considered as little more than craftsmen and a craft; but they were indemnified for the want of honours by the dignity of their employment, by commissions to decorate churches, convents and public buildings.

### Inigo Jones on Stonehenge.

Inigo Jones, with a boldness which rivalled the most intrepid antiquarians, declared Stonehenge to be a temple of the Tuscan order, raised by the Romans some time between Agricola and Constantine, and consecrated to the god *Cœlus*—the origin of all things. To support this theory he had learning at command, some skill in illustration, and, more than all, that scientific knowledge which commands respect in such an inquiry. It is wonderful with what plausibility he gradually smooths those rude and colossal masses of scabbled stone into a work of the Tuscan order. First, he alleges that no other people save the Romans were capable in those times of erecting such a work. The magnificence of the conception, the order of which it was composed, the science displayed in its construction, the double portico in the greater circle of stones, a similar portico in the cell or hexagon, the manner and position of the columns and the Roman reliques found in the neighbourhood, all pointed to that people. Secondly, he concludes it to be a temple, from the interval or spacious court round about, the cell and its porticoes, the altar and its position eastward, the aspect of the whole fabric and the skulls of beasts found in the surrounding soil. And thirdly, he contends that the temple was dedicated to the god *Cœlus* because of the situation, the decorum of the structure, the pyramidal figure of the stones and the nature of the sacrifices. The knowledge of architecture which he squanders upon this subject is immense. It was evident that Stonehenge never had a roof—but then the Eleans had one temple and the Thracians another of open columns and without covering—the architraves of Stonehenge were laid without cement—so were several structures of Classic times—the portico of Stonehenge is double—so was the temple of Jove built by Augustus Cæsar, and so was the Pantheon at Athens—

the square and tapering columns of Stonehenge, could be nothing save Tuscan, for any one might see they were neither Ionic nor Corinthian—and then the Italians of old were the sole inventors of the Tuscan order, and consequently the Romans could not well do otherwise than use it in a structure consecrated to the chief god. "Furthermore," says Inigo, "if we cast an eye upon the Roman artifice and manner of workmanship, Stonehenge appears built directly agreeable to those rules which they observed in great works; for the Roman architects in distinguishing the manner of their temples always observed, as Vitruvius in his third book teaches us, the greater the columns were the closer they set them together; so in this antiquity, the stones being great, the spaces between them are likewise narrow. I suppose I have now," he continues, "proved from authentic authors and the rules of art, Stonehenge anciently a temple dedicated to Coelus and built by the Romans, the magnificence of whose stately empire is this day clearly visible in nothing more than in the ruins of their temples, palaces, arches, triumphals, aqueducts, thermæ, theatres, amphitheatres and cirques, and other secular and sacred structures. As I have delivered my own judgment freely, all reason other men should enjoy theirs; but those who sail in the vast ocean of time, steering their course betwixt anciently approved customs and convincing arguments, guided by good authority and sound judgment, arrive much safer and with better repute in the secure haven of undoubted truth than those who listen to traditions and fables and take vulgar belief for certainty." That an architect of such natural genius and good sense as Jones should see in Stonehenge the visible remains of a magnificent Roman temple of the Tuscan order seems almost incredible. But in his day we had had no opportunity to observe, as India has since enabled us to do, the processes whereby comparatively rude nations are able to heap up enormous structures, which modern eyes would at once pronounce to have demanded all the appliances of art; and this may account for the incapacity of such men even as Inigo to recognise on Salisbury Plain the primeval efforts of some populous horde of barbarians—on whom the light of science was beginning to dawn, who were not without natural aspirations after grandeur, and the raw germ of whose rude structures and marauding ballads was predestined to find complete development in the York Minsters and the Marmions of some distant age.

#### Egyptian Sepulchral Tablets.

These tablets, "huta," were used for the same purpose as tombstones and sepulchral monuments at the present day, but distinguished by having been placed inside the tombs and not outside and in the open air. They are different materials, as granite, sandstone, alabaster and limestone, and of different sizes and shapes, square, rectangular, and either pointed or rounded at the top; those of square shape often representing the entrance or cornice. At a later period (about the twenty-second dynasty, or in the ninth and eighth centuries B.C.) wooden tablets made of sycamore were substituted. These tablets are generally rounded above, and surmounted by a wooden figure of the baieth, or soul, and stand on a pedestal of two small flights of steps, into which they are inserted. They have been covered with linen, coated with plaster, on which have been painted in tempera the vignettes, or pictures, and inscriptions. The principal subjects represent the deceased attended by his mother, wife, sister, or brethren standing in adoration to the boat of the Sun, or to the solar deities Ra, Sekar or Socharis Tum, Atum or Tomos, and Osiris, either alone or accompanied by his wife Isis; Nephthys, Anubis, Amset, Hapi, Tuautmutf and Kabhsenuf, and other sepulchral deities. The texts accompanying these scenes are the names and titles of the deities and of the deceased, usually placed in the scene along with them, and a larger inscription in horizontal lines of hieroglyphics, placed under the scene, being a proscynema or act of adoration to the principal deities to confer the usual benefit of food, permission to pass from Hades or off the earth, and for the soul to go to heaven or the empyreal regions. Some inscriptions are adorations or hymns to the sun. The name of the deceased on these tablets is preceded by the title of Osiris, in whose condition he was supposed to pass after death; but about 100 B.C. females began to have the title of Athor, or the goddess of beauty, prefixed to their names. Some of these tablets were surmounted on the rounded top by the figure of a human-headed hawk, emblem of the bai or soul, fixed by a plug into the upper rim of the tablet.

#### The Olympic Games.

There is a difference between the moral basis on which Greek antiquity rests, and our modes of life and thought in modern times. We men of to-day can hardly even conceive how the Greeks, the most intellectual nation the world has seen, could make their highest national festival a gymnastic one, far less can we sympathise with or imagine ourselves taking actual part in this truly Bacchic enthusiasm for the Olympic victor. We have lost all living and immediate sympathetic relation to

the Olympic games, because gymnastics with us no longer occupy that position which they held in so eminent a degree among the Greeks. It is not by any means mere bodily strength and agility which forms the basis of the Olympic games. The coarser, merely mechanical and one-sided species of gymnastics which aims solely at an athletic development of the corporeal frame, and was in later times so greatly in vogue among the Romans, was, in the Greek estimation, contemptible; they looked on it as "banausian," that is, unworthy of a freeman. Gymnastics among the Greeks had a highly ideal basis. They were the source of central interest in the Olympic festival, simply because they were in reality the focus in which all the rays of the moral, artistic and political life of the Greeks converged. The Greeks were so thoroughly artists by nature that they could not think of beauty of soul except as co-existent with beauty of body. Aristocracy of mind was with them at the same time essentially an aristocracy of personal beauty. Even an Aristotle could give utterance to the famous sentiment that it was a faulty arrangement in nature to bestow, as she frequently does, on slaves the beauty of freemen, and that if there existed men surpassing all others in beauty, as much as the statues of the gods surpass mortals, all men would of necessity and of right be subject to them. For the Greeks, the beautiful was the good and the good was the beautiful; their highest moral idea was the good and beautiful man. The practice of gymnastics, therefore, of which the end and aim was the beauty of the body in carriage and movement, was at once the privilege and the duty of the freeman. Gymnastic education was the essentially necessary and natural complement of the "musical," i.e. whatever fell within the region where the muses presided. It educates, not only for physical, but for physical and moral availability. It was worth, at once physical and moral, that the Greeks so highly admired in the Olympic victor. He was for them, par excellence, the good and true man.

#### Tan Chet Qua.

Roubilliac was very greatly esteemed. His kindness and liberality towards the students in his own department endeared him particularly to the rising school of sculptors. Amongst others who derived advantage from his tuition and advice was Tan Chet Qua. This ingenious native of the "celestial empire" was the first who studied the fine arts in England. His talents were multifarious, as he not only practised sculpture and portrait painting in oil and miniature—admitting that light and shadow were not incompatible with painting, which was against the doctrine of Chinese practice—but also studied other arts and sciences. He read a paper of his own writing on the subject of oriental gardening, and it is said afforded useful hints to Sir William Chambers in his celebrated treatise on the same subject.

#### GENERAL.

**The Superintendent of Buildings** of New York reports that in 1896 plans were filed for 3,144 new buildings, of an estimated cost of 73,781,945 dols. Three thousand three hundred and eight buildings were completed during the year.

**The Wallace Collection**, which now belongs to the nation, has been valued, it is said, at 4,000,000/. To contain such a gift the upholding of Hertford House as a museum will not be considered as a waste of public money.

**The Annual Excursion** of the members of the Northern Architectural Association will be made to Bamburgh on July 3.

**Messrs. James & Sweet-Escott**, architects, Cardiff, have been successful in the competition for the best design for the new law courts in Halifax. The second and third prizes were awarded to local architects.

**The Treasurers** of the St. George's Hospital have received from the executors of the late Mr. David Brandon, architect, the sum of 10,000/., being a payment on account of the residue of his estate, one-sixth share of which he had bequeathed to this hospital, in addition to a specific bequest of 3,000/., already received.

**The Sandell Photographic Exhibition** will open on or before July 12; at the Modern Gallery, 175 Bond Street, and will consist of over 400 subjects, the majority never before photographed, including the City Companies' Halls, the Guildhall and Mansion House, Lincoln's Inn, Gray's Inn, Lambeth Palace, Westminster Abbey, Windsor Castle, the Monuments in St. George's Chapel, and the Albert Memorial Chapel, Windsor; the Royal Mausoleums, Frogmore; St. Peter's, Rome; St. Mark's, Venice, &c.

**Messrs. Waller**, architects, of Gloucester, have received instructions to prepare drawings and superintend the erection of the Free Library on the south side of the Science and Art School in that city.

# THE Architect and Contract Reporter.

## EDITORIAL NOTICES.

*The authors of signed articles and papers read in public must necessarily be held responsible for their contents.*

*No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.*

*Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.*

## TENDERS, ETC.

*\*\* As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than 2 P.M. on Thursdays.*

## NEW READING CASE.

To Librarians of the Public Libraries and Reading-rooms.—A new handsome Reading Case can be supplied at a nominal charge of 2s., by post 2s. 6d., on early application to the Publisher, 175 Strand, W.C.

## VARIETIES.

MR. J. T. PASSMORE, the well-known estate agent of West Kensington, has taken into partnership Mr. H. J. Cookes, who for eight years has been with Messrs. Debenham, Tewson, Farmer & Bridgewater. The style of the firm will be "Passmore & Cookes," and they will carry on their business as auctioneers, estate agents and valuers at Avon Lodge, West Kensington, W. (two doors from the railway station).

AT St. Mary's, High Crompton, a stained-glass west window has been unveiled. The window represents eight scenes in the life of St. John the Evangelist. The cost is 332*l.* 14*s.*

AN important feature of the improvements now being carried on in St. George's Church, Edinburgh, is the filling with stained-glass of the large window of three divisions looking to the west. By somewhat enlarging the height of the central opening sufficient space has been obtained for the representation of the subject of the Ascension. The composition divides itself into two important groups. The upper one, elliptical in its main lines, consists of our Lord, in the act of blessing, surrounded by a group of angels, whose wings of varied colour, mostly blue, become a background emphasising the principal figure. A band of cherubs and cloud forms of varied rubies separate the upper from the lower group, which latter consists of Apostles and the Virgin Mary, some kneeling, others standing, but all with upturned faces concentrated on the ascending figure. The deep full colour-scheme of the lower group, especially those of two kneeling figures in the foreground—the one of a rich blue passing into purple, and the other of a golden yellow passing into the deepest ruby—have been much admired. The side spaces are filled with classic ornament upon a coloured ground, the emblem of the burning bush and a shield bearing the cross of St. George forming central features. The whites used are all of an especial thick character, with the object of breaking up and diffusing the direct rays of the sun, and yet allowing of sufficient light tints being introduced, which the nature of the subjects requires. The window was executed under the direction of the architect, Mr. Leadbetter.

MR. T. BATTERBURY, F.R.I.B.A., F.S.I., hitherto practising at 29 John Street, Bedford Row, has removed his offices to Imperial Chambers, 47 Chancery Lane.

A NEW theatre is to be erected in Aberdeen on a site which has been recently acquired for the purpose on Rosemount Viaduct.

It has been decided to build a seaside home for delicate children in connection with Mr. Spurgeon's orphanage. About 10,000*l.* will be required to purchase the land and complete the home.

A NEW Moravian church has been formally opened at Bristol, which has been erected on the site of the old chapel in Maudlin Street, at a cost of 2,000*l.*

THE name of papyrolith is given to a novelty in flooring material which has lately been invented by Otto Kraner, of Chemnitz, the article being a special preparation of paper pulp, which is in the form of a dry powder; when mixed with water it may be spread like mortar over stone, cement or wood, where it dries quickly and may be smoothly planed, besides which it may be tinted almost any colour, in this way adapting it for parquetry with variegated borders, or for panels and mosaics. Among the various advantages claimed by the inventor for the use of this product are freedom from crevices, deadening of noises and poor conduction of heat, also considerable elasticity, safety from fire and remarkable durability. It may be employed, too, for wainscoting and other architectural purposes, as well as for flooring.

ON the occasion of the fiftieth anniversary of its foundation, the Russian Archaeological Society has received the congratulations of a special deputation of the Royal Historical Society of London. Congratulations were also received from many other learned associations.

IT has been found necessary to put Great Paul under repair. It appears that the metal of the bearings by which the big bell is suspended from the supporting beam above expanded alarmingly during the very hot weather, and the chilly weather that followed caused these bearings to subside an inch or two into the socket.

THE work of extension at the Prince's Landing Stage, Liverpool, was practically completed last week by the connection of the stage with the high-level jetty by an iron bridge 150 feet in length.

THE Dibble memorial window, erected by cyclists in Ripley Church, was unveiled at a special service.

EARL RUSSELL'S attractive little residence, Amberley Cottage, close to Boulter's Lock, Maidenhead, was last week almost totally destroyed by fire. The bedrooms and downstairs apartments were gutted and the furniture totally destroyed. The Earl's valuable collection of books was fortunately saved,

and the electric-light installation adjoining the house was not damaged in any way. A new wing had only recently been added to the building and it was thought that the flames originated here.

OWING to heavy rains a new sewer in course of construction near Sefton Park, Liverpool, to cost 20,000*l.*, having burst, the further rainfall caused lands and houses adjoining the park to be inundated. Aigburth Road neighbourhood was covered with debris and sludge from the culvert; walls have been knocked down and barricades swept away. In some parts there has been considerable subsidence, the foundations of a few villas being rendered insecure.

A NEW district fever hospital, which has been erected near Camelon by the eastern district committee of the Stirling County Council, was formally opened on the 22nd ult. The hospital, which is situated on the Edinburgh and Glasgow Road, a little to the west of Camelon, is built on a site covering three acres. It consists of four blocks of buildings, viz. administrative block, scarlet fever block, enteric fever block and laundry block. The hospital has been fitted up with all latest and most approved appliances and conveniences, and in connection with it there is a patent disinfector, and an ambulance waggon has been specially constructed for the conveyance of patients. The architects were Messrs. A. & W. Black, Falkirk, and the total cost of the hospital, including furnishing, is estimated at about 7,500*l.*

ABOUT one o'clock on Christmas morning the inhabitants of Bank Buildings, Bank Street, Clydebank, and vicinity were greatly startled by a loud noise, as of cannonading. The people rushed to their doors to discover the cause, when it was ascertained that a three-storey red sandstone building, now in course of erection at the corner of South Bank Street and Dumbarton Road, had collapsed, leaving only a part of the wall next the latter road intact. The primary cause of the disaster it is difficult to ascertain—whether it was in the nature of the soil or the details of the construction. The building, however, is said to have shown signs of instability recently, and the workmen took the precaution to leave the job and attempt to shore up the premises.

AN incredible story has got abroad to the effect that the Capitol of Washington State is built upon a reef which contains deposits of gold, and may have to be removed.

# KETTON FREESTONE.

THIS STONE HAS NO EQUAL FOR BUILDING AND MONUMENTAL PURPOSES, AND BLOCKS OF ANY SIZE CAN NOW BE SUPPLIED. SAMPLES AND FURTHER PARTICULARS WILL BE SUPPLIED ON APPLICATION TO

## T. C. MOLESWORTH & CO., KETTON, RUTLAND.

Extract from a Paper on Masonry read before the Architectural Association at 9 Conduit Street, Regent Street, London, on March 6, 1896, by Mr. HERVEY FLINT, Teacher of Masonry to the Worshipful Company of Carpenters and the Battersea Polytechnic.

"Ketton Stone is one of the best weather stones we have, but it is one that is rather neglected by the Architect. The oolite formation of this stone is very perceptible. We have examples of it at St. Dunstan's Church, Fleet Street, St. Pancras Station, and I was much impressed recently on a visit to the Jews' Cemetery at Willesden by a large balustrade full of good detail, round Baron Rothschild's enclosure; it has been standing some twenty-five years and is in a perfect condition, the carving and arrises are as sharp as when executed, and I would strongly commend this stone, as it combines the essentials of durability with a nice warm cream colour."

Telegrams, "SANDBAGS, LONDON."

Prices on Application.

Limited, contains much information about local government, and the memoranda printed in the diary should be enough to prevent any neglect of public duties.

THE Rugby Cement Company, Rugby, are sending out a very handsome calendar. It is substantially mounted, well varnished, and is made ornamental by means of several well-executed chromo-litho views of quarries, factories, &c. The Limmer Asphalte Company, of 2 Moorgate Street, have one on similar lines, but in this case the views are in black and white.

THE Belgian Minister of Public Works has decided to increase the accommodation at Antwerp Docks by extending the quays 3,000 feet to the south, at a cost of four million francs. A channel 200 feet wide and 24 feet deep is to be constructed. The present works are only part of a scheme for a still greater extension of the port, surveys having been made further down the Scheldt.

Two beautiful monuments have been placed in Middle Claydon Church to the memory of the late Sir Harry Verney and his second wife. The first is a bronze portrait in bas-relief, showing, almost in profile, the striking features that were endeared to many in the county. The second is a cross of black Derbyshire marble of antique form, inlaid with natural passion-flowers, mounted on a bracket bearing an engraved brass.

THE large mansion-house of Crossburn, near Troon, the property of the Duke of Portland, was on Wednesday last entirely destroyed by fire. It is supposed that the men, who had been making preparations for a new tenant, had left a fire burning during the night, and that something had become ignited.

MR. W. H. COLLIER has been appointed manager of both the Ship Canal and Bridgewater Departments of the Manchester Ship Canal Company. Mr. John C. Willson will continue to occupy the position of assistant manager. The following appointments have also been made:—Mr. John Oldfield to be superintendent, Bridgewater Department; Mr. Herbert M. Gibson, to be chief traffic agent, Ship Canal Department. Mr. Marshall Stevens has relinquished his appointment as manager, having entered into an engagement to develop the Trafford Park Estate, which adjoins the Ship Canal from the Manchester Docks to Barton.

THE church of the Immaculate Conception, Stonehaven, was reopened on the 27th ult., after having undergone extensive internal improvements. The alterations include four

beautifully stained-glass windows, embellishment of the sanctuary, &c.

THE roof of one of the annexes of the convalescent ward of East Pilton Hospital, Ferry Road, Leith, was destroyed by fire on Sunday last. By the arrival of the Leith Fire Brigade, the flames were prevented from spreading to the ward, the inmates of which were for some time in a state of considerable alarm. The fire is supposed to have originated in the overheating of a flue.

SIR HORATIO LLOYD having suggested, at a meeting in Chester a fortnight ago, the erection of a statue of the Duke of Westminster, as a mark of the esteem in which he is held and the gratitude felt for many noble works in the county and city of Chester, the proposal was taken up by the public with much enthusiasm and earnestness. The Duke, however, while feeling deeply the friendly spirit which has been so widely evinced, has communicated to Sir H. Lloyd his reasons for desiring that the movement should not go forward; and the promoters have, in deference to His Grace's strongly expressed wish, resolved, though most reluctantly, to deny themselves the proposed gratification.

### TRADE NOTES.

THE Isolation Hospital, Crewe, is being warmed and ventilated throughout by means of Shorland's patent Manchester stoves, with ornamental tiled sides and with descending smoke flues, the same being supplied by Messrs. E. H. Shorland & Brother, of Manchester.

WE have been requested to announce that Messrs. Milner & Co., Limited, the well-known safe manufacturers, have had to remove their offices in Manchester, owing to want of room. They have now large and commodious show-rooms at 15 Victoria Street, where all communications should be addressed.

A *propos* of the rumoured dearth of bricks in the London market, Messrs. Eastwood & Co., Belvedere Road, write us that "In consequence of the great demand for bricks, the large orders already booked by them, and the shortness of make through the excessively wet weather in September and October, they are compelled to withdraw all quotations. They can only quote from day to day, and can only accept orders subject to their having the bricks and being able to deliver. Orders will be loaded in rotation as received, and they cannot accept any liability for delay in loading or delivering."

MESSRS. NOYES & CO., 76 Old Street, London, E.C., have purchased the business of Messrs. Chambers & Co., the well-known makers of wall-ties, and are in a position to supply customers of the late firm with accuracy and despatch. They are just issuing a comprehensive illustrated catalogue of builders' ironmongery, which includes, amongst many other sections, cast-iron rainwater pipes, &c., register stoves, mantel registers, tiled register stoves, marble chimneypieces, ranges, kitcheners, bath and lavatory fittings, water-waste preventers, &c. We shall in an early number refer more fully to the specialties issuing from this firm.

We have been favoured with a copy of the third edition of "Notes of the Water Supply of the South of England, with Remarks on the Geological Formations Connected Therewith," by Edward Margrett, hydraulic and sanitary engineer, Reading, which contains valuable information respecting this all-important subject, particularly as regards obtaining supplies by means of artesian wells, and which will well repay perusal by members of the profession.

MESSRS. S. J. WARING & SONS, LIMITED, have taken over the old-established business of Messrs. Marler & Bennett, 175 and 176 Sloane Street, and are selling off the old stock at greatly reduced prices, previous to extensive alterations to the premises. Any of our readers who are on the look-out for bargains should take advantage of this opportunity.

MR. SAMUEL HUNTLEY ROWLEY, who was for some twenty-three years sole managing partner in the firm of James Woodward & Rowley, is now trading on his own account solely. All the old workmen, foremen and office staff remain with him, and the goods supplied by him will be of the same high quality as heretofore. His new works are situated close to Swadlincote station.

### BUILDING AND BUILDERS.

THE will of the late Sir Francis Lycett having placed a large sum of money at the disposal of the Wesleyan Metropolitan Chapel Building Fund committee, which by the decease of Lady Lycett is now available for extension purposes, the committee is prepared to give special stimulus and assistance in all new schemes that may be undertaken. For some time past a number of eligible sites have been held, in all about twenty, and others are being secured. At their recent meeting this

great connexional committee adopted the following resolution:—"That in consideration of the recent large addition to the Metropolitan Chapel Building Fund by the payment of Sir Francis Lycett's legacy, and that an impulse to chapel building, both on sites already held and unoccupied, and also on other sites that may be procured amidst neglected swarming populations, is urgently and immediately desirable, this committee is prepared to increase its usual grants by an additional sum of 500*l.* for each chapel to seat 1,000 persons, and by a proportionately smaller sum for each smaller metropolitan chapel, provided these chapels be commenced within the next two years." It is understood that some 80,000*l.* have already been received from the Lycett bequest.

### DIARIES FOR 1897.

If other reminders were not forthcoming, the appearance of diaries would be enough to suggest the coming of the new year. Among those received it is not easy to make a selection. In style there is none to surpass the "Architects, Surveyors and Auctioneers' Diary and Almanac," published by Waterlow Bros. & Leyton, Limited. The information appended would form a small volume. Messrs. Hudson & Kearns as usual have prepared several varieties of diaries which are adapted to professional practice whether large or small. They all uphold the reputation of the firm as publishers. Messrs. Finch & Co., Limited, of Lambeth, have also issued a diary, in which a good deal of memoranda relating to sanitation is introduced. Messrs. Spon have allowed extracts to be taken from their "Price Book and Surveyors' Handbook." Messrs. Crosby Lockwood & Son's "Price Book," if not a diary, is an annual which is in everyday use. This year the editor announces that he has recognised the advance in wages in calculating prices. As trade is very brisk and "the markets for many kinds of materials are rising, and there is every prospect of a busy time during the present year," it is to be hoped profits will be proportionately large. The flood is rising which leads to fortune, and they will be unwise who neglect the opportunity it offers.

MR. THOS. ELSLEY, late of Great Portland Street, notifies us that he has removed to his new premises at 28 Great Titchfield Street, W.

### THE PLUMBERS' COMPANY.

ON Tuesday last, in accordance with a resolution passed by the Court, the freedom and livery of the Plumbers' Company were conferred, at the quarterly Court, held at the Guildhall, on ex-Bailie Crawford, late chairman of the health committee of Glasgow. The resolution, which was read by the clerk (Mr. W. R. E. Coles), set out that the honour was conferred on Mr. Crawford "in recognition of his timely aid and eminent encouragement of the movement for the national registration of plumbers by personal efforts and official influence, securing the alliance of the representatives of the health and educational authorities and plumbers of the locality with the district council for Glasgow and the west of Scotland, and the active co-operation of that body and others in promoting the higher technical training of plumbers, and the certification of qualified men, in the interests of the public health." Mr. Philip Wilkinson, master of the company, presided, and spoke of the useful work which Mr. Crawford had done as chairman of the health committee of Glasgow. Mr. C. Hudson, Alderman Sir Stuart Knill, and Mr. W. H. Bishop also bore testimony to Mr. Crawford's valuable services in the cause of sanitation. The customary oath having been administered by the clerk, Mr. Crawford was formally admitted by the Master as a freeman and liveryman of the Plumbers' Company. In thanking the Court for the honour conferred on him, Mr. Crawford referred to the progress made in sanitary matters during the past few years as being largely due to the work of the Plumbers' Company. Their efforts to impart technical instruction to plumbers had necessarily been of advantage to the community as a whole. He believed every householder was now beginning to realise that it was his business to ascertain that the plumber he employed was a fully-qualified man. The freedom of the Company was afterwards conferred on Mr. Collins (sanitary inspector to the Camberwell Vestry) and Mr. W. Moss (of Manchester), they having become entitled to it through having passed the examinations in practical workmanship and knowledge of plumbing prescribed by the company.

### ELECTRIC NOTES.

ELECTRIC lifts are now coming largely into use, and owing to their economy in working are fast superseding the hydraulic type. The new infirmary of the Halifax Union is to have six passenger lifts and two service lifts all actuated by electricity.

The whole of the work, including all motors and gear, will be made and fitted up by Messrs. Easton, Anderson & Goolden, Limited, of Erith, who are also supplying amongst other electric lifts three for passengers and one for goods at the new mansions now in course of erection at Bedford Court, W.C., and one for passengers at the Manchester Technical Schools.

AN exhaustive report, prepared at the instigation of the Douglas Town Council by Mr. Thos. H. Nesbitt, town clerk, has been issued on the electric lighting of Douglas, Isle of Man. A large quantity of information received from the town clerks of Liverpool, Manchester and other important centres has been collected and analysed, with the result that the report recommends the adoption of the electric system of lighting on grounds of cleanliness, by reason of the absence of deleterious fumes, and on grounds of purity, steadiness and safety, as compared with other methods of lighting. As a health and pleasure resort, Douglas would be incalculably benefited by the adoption of the electric light, and the beauty which already characterised Douglas Bay would be enhanced. With perhaps the exception of the Bay of Naples, the report says, no place lends itself so admirably to effective lighting as Douglas Bay. Continuing, the report is in favour of the municipalisation of all public undertakings, including electricity, workmen's dwellings, public baths and waterworks. Nearly all the more recent electric installations were being carried out by municipal authorities by means of public funds. In Douglas, however, the report states, exceptional circumstances prevail, and the Isle of Man Tramway and Electric Power Company, who are known to be favourable, should be entrusted with the work of supplying Douglas with electric light on satisfactory terms being agreed upon. This course would be the wiser, bearing in mind that the present indebtedness of Douglas is 290,000*l.*, which the estimated expenditure on necessary works would bring to 450,000*l.*

Mr. J. ST. LOE STRACHEY having offered to decorate the walls of the refreshment-room at the mansion in Brockwell Park with pictures to be painted by his brother, Mr. H. Strachey, the work has now been carried out. The pictures represent scenes of country life connected with haymaking, and are executed in oil-colours on canvas. The portions of the walls not covered by the panels have been coloured to harmonise with the paintings.

### THE "DEFIANCE" PATENT. HYDRAULIC WATERTIGHT FLOOR SPRING AND CHECK.

Size of Plate,  
12 x 8 in.  
Size of Box,  
10 1/2 x 6 x 3 1/2 in.

906  
80/-  
With top centre  
and brass shoe any size.

This Floor Spring is suitable for any sized door up to 2 1/2 inch thick and can be regulated to suit any force required by means of the capstan at end of box.

The box is perfectly watertight and weatherproof, which is a distinct advantage when fixed in Banks, Board Schools, Libraries, and similar places, where the floors are frequently washed down.

Working Models of these and other Specialties may be seen at our newly-fitted London Showrooms, 57 HOLBORN VIADUCT, E.C.  
Architects and Buyers are respectfully invited to inspect same.

## AMERICAN BUILDING.

A REPORT has been prepared by a committee of experts on the new City College, Baltimore. Already several dangerous defects are seen in the buildings, including settlement and shrinkage of the walls, which show large cracks; insecure foundation; the crushing of work under the iron girders; inferior mortar; arches too flat, weak and treacherous; wrought-iron bars instead of cast-iron lintels, which are not sufficient to stand the weight likely to be imposed upon them; terra-cotta work done by incompetent persons in a careless manner; ironwork not up to the standard required by the building law; bad carpenters' work, the window frames being out of plumb; old trusses and salmon, or soft bricks, in large numbers. Besides there is evidence of general incompetence in the supervision, which permitted the contractor to ignore the specifications and practically do as he pleased. The report does not attempt to fix the responsibility for so discreditable a state of affairs on individuals.

## BUILDING IN MANCHESTER.

THE extraordinary activity of all branches of the building trade in Manchester during the past twelve months cannot be paralleled, says the *Manchester Guardian*, by any more recent reference than one to the years 1876 and 1877, when many of the suburbs round the city may be said to have had their birth. In the city several very large structures have been completed and others begun, while a considerable quantity of rebuilding of warehouses, offices and shops has been in progress. In offices of all descriptions the hydraulic lift, now readily worked by the public high-pressure supply, bids fair to become universal, and an immense amount of alteration to make room for it has been carried on. Iron and glass continue to supplant heavier materials, especially in the building of shops. The attempts to give elegance as well as individuality to the designs of shop fronts have become very numerous; but it may be noted that local contractors have lagged behind the times in this special department, Birmingham and London firms being generally employed to do work of this kind of the best class. In the suburbs, the designs even of the cheapest classes of cottage property show in many cases considerable improvement upon the styles that have been too long in vogue.

Thousands of new houses have sprung up, built to let at rents usually ranging from 5s. 6d. to 7s. 6d. per week and the rule has been for them to be taken considerably before completion by bodies of tenants newly immigrated to the town. There has been practically no desertion of older property of this class, which remains fully tenanted. As may be imagined, labour has been abundant all the year, at hardening rates. Bricklayers have been better paid, and plasterers, whose numbers are, by the rules of their society, strictly limited, have often been in very urgent request. The demand for such favourite materials as Ruabon bricks has not slackened, in spite of the production of large quantities of imitations by makers of various shale bricks in Accrington and Burnley. There is every appearance of continued prosperity throughout the building industries in Manchester. The demand for house accommodation shows no sign of abatement, and in the city some enormous contracts are about to be given out.

## TALL BUILDINGS IN CANADA.

THE completion of a ten-storey building in Toronto and the proposal to erect a fourteen-storey structure on the site of the present St. Lawrence Hall Hotel, in Montreal, would, as the *Canadian Architect* points out, be evidence that the craze for tall buildings which has marked Chicago and New York for several years past, is exerting its influence upon the architecture of our Canadian cities. It may not be out of place at this juncture to point out that in the American cities we have named popular favour is being withdrawn from these abnormal specimens of nineteenth-century architecture, and legislation has been introduced for the purpose of restricting the height to which buildings may be erected in the future. Another potent influence tending to discourage this style of architecture is that the number of such structures already built so far exceeds the demand that the owners are said to have been compelled to reduce rentals by 50 per cent., while some of the high structures in Chicago which were designed for office purposes are being used as storehouses, in which capacity it will of course be impossible to obtain a fair return on the owners' investment. The unsatisfactory experience of our American neighbours in this direction, coupled with the lower land values in Canadian cities, would seem to render inadvisable the erection of structures exceeding, say, six or eight storeys in height.

## NEW CATALOGUES.

THE new editions of Messrs. Moreland & Son's catalogues generally exemplify some of their latest constructive works. Among those shown in the new issue is the steel construction of a mansion for Mr. B. I. Barnato, in Park Lane, in which columns and beams have to be of exceptional strength. The principals of the Northampton Institute, Clerkenwell, have spans of 65 feet and are 19 feet 6 inches apart. The roof of a saw mill in Northampton has a clear span of 61 feet. In another at Tottenham the spans are 47 feet, with two of 25 feet each. The trusses for the new Shakespeare Theatre, Lavender Hill, are 56 feet span. A stanchion in Barclay, Bevan & Co.'s bank carries 250 tons. It is provided with a metal base which stands on the concrete, and thus stone bases are unnecessary. The stability is increased by the arrangement. In all cases Messrs. Moreland refer to actual examples. As usual, there are several elaborate tables of safe loads for girders, columns and stanchions, and it is guaranteed that the sections will carry the loads specified. The catalogue is, therefore, a trustworthy guide to those who require efficient construction in steel, and a record of what has been done by the firm in difficult and remarkable cases.

## SURPLUS LANDS OF MANCHESTER SHIP CANAL.

THE Bill which has been deposited by the Manchester Ship Canal Company contains three clauses relating to the surplus lands of the company. It is provided that with the previous consent in writing of the Corporation of Manchester the company

may, in addition to any moneys which they may have been authorised to borrow in pursuance of their Acts, from time to time borrow any money on the security of all or any of their surplus lands, and for the purpose of securing borrowed money and interest thereon may mortgage or charge such surplus lands to any person or company advancing such moneys. It is also provided that the company may grant leases of any lands belonging to them for any terms not exceeding ninety-nine years to any persons, corporations or companies who shall covenant to improve such lands by laying out money in the construction of docks, basins, lay-byes, shipyards, wharves, landing-places, warehouses, sheds, or other buildings calculated to promote or facilitate the business of the company, and they may grant to such lessees the use of any wharfage, quayage, or other space requisite for their trade. As regards the application of moneys it is proposed that all moneys received by the company in respect of any mortgage or charge made in pursuance of the Act and not required for any other purpose of the company shall, at the request of the Corporation of Manchester, be applied in the first instance to the redemption of the new debentures in the hands of the Corporation, and, subject to any such request, in paying off the moneys borrowed by the company on mortgage or redeeming any debentures or debenture stock now or hereafter to be issued by the company in order of their priority.

## SAND BRICKS.

A COMPANY has been incorporated in San Francisco, that proposes to expend 50,000 dols. in the purchase of a site and the erection of buildings for the manufacture of bricks from sand. The stone brick which it is proposed to make will be manufactured from powdered stone or the elements contained in stone, such as sand, clay, &c. These substances are mixed with a prepared "flux," which acts as a bond, holding together the particles of sand or other material used as a filler, the whole being thoroughly annealed by heating.

Among the advantages claimed for the bricks is the saving of time, only ten hours being needed for their manufacture instead of eight to thirty days, a much less consumption of fuel, scarcely any loss from burning, a crushing strength from 10,000 to 40,000 lbs. to the square inch instead of from 400 to 4,000 lbs., and a reduction of cost to three-fifths of that of the old style bricks.

## THE ROYAL INFIRMARY, MANCHESTER.

THE chairman of the special committee of the Manchester City Council appointed to represent the interests of the citizens in regard to the proposed rebuilding of the Royal Infirmary, Sir John Harwood, has been waited upon by various gentlemen, who urge that the city should become the possessor of the whole of the Infirmary site in Piccadilly. The suggestion was made to Sir John Harwood that if the Infirmary Board and Trustees were now as much inclined to part with the site as they were in 1875—when it was offered to the Government for post-office purposes—wealthy citizens would come forward and subscribe a large portion of the purchase-money. The Corporation would be asked simply to complete the payment. Sir John Harwood was good enough to state to a representative of the *Manchester Guardian* the point of view from which he regarded this proposal. The Corporation, he said, had never as a corporation had this project under consideration. Certainly it had never been put before them in such a form as to elicit an expression of opinion. "I am convinced," he said, "from my long experience that, if the assistance of the Corporation were sought to maintain the present open space on Piccadilly, the matter would be considered and dealt with in a reasonable way. There is no disposition whatever to deal with the infirmary board, or, indeed, with any other responsible authority in the city, in other than a conciliatory and reasonable manner. The Corporation only desire to be considered as co-workers with others for the general good of the community."

The trustees of the Manchester Royal Infirmary have voted on the question of a rebuilding and extension on the site in Piccadilly, in accordance with the plan submitted by the grand committee. A small majority of the trustees who polled have declared in favour of the proposal. The resolution which Sir Frank Forbes Adam submitted to the special meeting of trustees held in the Memorial Hall on the 14th instant was as follows:—"That this meeting of trustees hereby sanctions the rebuilding of the Manchester Royal Infirmary on its present site, in accordance with the plan submitted by the grand committee, and authorises the board of management of the Manchester Royal Infirmary to take steps to carry out the work with such modifications in detail as may from time to time appear to them to be desirable." Mr. B. Armitage (Chomlea) seconded the resolution. An amendment in the following terms was moved by the Lord Mayor of Manchester (Mr. Alderman J. F. Roberts) and seconded

by Sir John Harwood:—"The trustees, upon consideration of the report of the grand committee, are of opinion that it is not desirable at the present time to extend the ground area of the existing infirmary buildings." Upon a show of hands the Chairman stated that the voting was so even that he was unable to declare whether there was a majority for or against the amendment, whereupon a poll of all the trustees was demanded by six trustees who were present at the meeting. On the voting paper issued the terms of the motion and amendment were set forth, and each trustee was asked to declare in favour of one or the other. The number of voting papers issued was 1,349, and of these 853 were returned. The counting took place yesterday morning, Sir Frank Forbes Adam and Mr. E. S. Heywood being scrutineers representing those in favour of the motion, and Sir John Harwood and the town clerk (Mr. W. H. Talbot) acting in the same capacity for those in favour of the amendment. The scrutineers rejected one vote as bad. It will be noticed that 496 trustees did not vote. The result of the poll was declared as follows:—

For the motion	449
For the amendment	403

This result will be submitted to a special meeting of trustees to be held in the middle of January.

## THE ORIGIN OF THE PLUMBER.

IN a paper on "The Evolution of Sanitation in Relation to the Plumber," read to the members of the Edinburgh and District Branch of the National Registration of Plumbers, Professor Glaister, of St. Mungo's College, Glasgow, discussed the origin of the plumber. An interesting study, he said, was afforded by the origin of new occupations in the advance of mankind from the primitive to the civilised, and not the least interesting aspect of the study was that presented by plumbing. Very early in the history of the world references were found to those who worked in metals—Tubal Cain was the first recorded example—and it would appear as if the ancients were particularly well acquainted with lead and its properties. The division of crafts in metals would be conjectured to begin with this metal because of its plasticity and obvious utility, and the lead-worker became literally a plumber—the Latin *plumbum* signifying lead—although as a matter of fact he was also an

SAVOY & COLES,

Steam Press, Cirencester.

artificer in brass, iron and zinc. Probably the earliest occupation was that of the builder, but as architecture became more ambitious in its designs, and the arts of the carpenter and mason were found insufficient to make fabrics watertight, the plumber found his occupation first in laying leaden roofs, afterwards in fitting pipes in some of the principal buildings which sprang up in the palmy days of Rome, and further in connection with those giant aqueducts which, as at Lyons and Rome, attest the engineering and sanitary achievements of the ancient Romans. With these as a starting-point, Professor Glaister traced in an interesting manner the career of the plumber through the ages to the modern era of sanitation and scientific plumbing.

### THE LATE SIR JOHN BROWN.

SIR JOHN BROWN, the great ironmaster and the pioneer of armour-plate manufacture for the defence of ships of war, died on Sunday at Bromley, Kent, aged eighty. His health had been failing for some years. Sir John, says the *Times*, was a native of Sheffield, and received his education at a local private school. He was first apprenticed to the factoring business, and afterwards engaged in the manufacture of files and table cutlery. The apprentice stepped so speedily to the front that on reaching his majority he was invited to become a partner, which offer he was unable to accept through lack of capital. His employer offered him his factoring business and volunteered money to carry it on. John Brown's father and uncle guaranteed 500*l.* to a local bank, and this modest credit was his start in life. In 1848 he invented the conical steel buffer spring. At the time no external buffer was used on railway lines, and for waggons there was no buffer at all. His were the first, and he was soon producing them at the rate of 150 sets a week. The first pair of conical buffers ever made went to Wales, the second to Scotland and the third to Ireland, the London and North-Western Railway leading the way in England. At this time he was engaged in various manufactures carried on in different parts of the town. In 1864 he concentrated the whole in Savile Street, where he acquired an establishment, afterwards extended and rechristened the Atlas Works, which covered 25 acres. It then occurred to the owner that the demand for iron would justify its production for steel-making purposes. He erected ten converting furnaces on the south side of the Midland Railway for supplying the wants of the town as well as of the

Atlas Works. The result of his enterprise was to make Sheffield practically almost independent of Sweden or any other country from which masses of iron for manufacturing purposes used to be drawn. This was also the beginning of the use of iron of Yorkshire quality for boilers and bridge plates, such as those used on Charing Cross bridge, which were partly supplied from the Atlas Works.
